Résumé

On considère une équation aux dérivées partielles stochastique possédant une non-linéarité de type logarithmique (ou une puissance négative), avec une réflexion en zéro sous la contrainte de conservation de masse. L'équation, dirigée par un bruit blanc en espace et en temps, contient un double Laplacien. L'absence de principe de maximum pour le double Laplacien pose des difficultés pour l'utilisation d'une méthode classique de pénalisation, pour laquelle une importante propriété de monotonie est utilisée. Etant inspiré par les travaux de Debussche et Zambotti, on emploie une méthode basée sur les équations en dimension infinie, utilisant l'approximation par des équations régulières et la convergence des semi-groupes de transition liés aux équations régularisées. On démontre l'existence et l'unicité de solutions pour des données initiales positives, et on donne plusieurs résultats sur les mesures invariantes et les mesures de réflexion.

Abstract

We consider a stochastic partial differential equation with logarithmic (or negative power) nonlinearity, with one reflection at 0 and with a constraint of conservation of the space average. The equation, driven by the derivative in space of a space-time white noise, contains a bi-Laplacian in the drift. The lack of the maximum principle for the bi-Laplacian generates difficulties for the classical penalization method, which uses a crucial monotonicity property. Being inspired by the works of Debussche and Zambotti, we use a method based on infinite dimensional equations, approximation by regular equations and convergence of the approximated semi-group. We obtain existence and uniqueness of solution for nonnegative initial conditions, results on the invariant measures, and on the reflection measures.

Introduction and main results

The Cahn-Hilliard-Cook equation is a model to describe phase separation in a binary alloy (see [6], [7] and [8]) in the presence of thermal fluctuations (see [11] and [25]). It takes the form:

$$\begin{cases} \partial_t u = -\frac{1}{2}\Delta(\Delta u - \psi(u)) + \dot{\xi}, & \text{on } \Omega \subset \mathbb{R}^n, \\ \nabla u \cdot \nu = 0 = \nabla(\Delta u) \cdot \nu, & \text{on } \partial\Omega, \end{cases} \quad (0.1)$$

where t denotes the time variable and Δ is the Laplace operator. Also $u \in [-1, 1]$ represents the ratio between the two species and the noise term $\dot{\xi}$ accounts for the thermal fluctuations. The nonlinear term ψ has the double-logarithmic form:

$$\psi : u \mapsto \ln\left(\frac{1+u}{1-u}\right) - \kappa u. \quad (0.2)$$

The deterministic equation has been extensively studied first in the case where ψ is replaced by a polynomial function (see [7], [25] and [30]) and then for non smooth ψ (see [5] and [15]). Furthermore, this model has been used successfully for describing phase separation phenomena, see for example the survey [29], and the references therein, or others recent results on spinodal decomposition and nucleation in [1, 4, 23, 27, 28, 33, 34, 35]. In the polynomial case, the concentration u is not constricted to remain between -1 and 1 and the logarithmic nonlinearity might seem preferable.

Up to our knowledge, only the polynomial nonlinearity has been studied in the stochastic case (see [2, 3, 9, 10, 12, 18]). This article is a step toward the mathematical comprehension of the full model with double-logarithmic term and noise. We consider the one dimensional case and consider a nonlinear term with only one singularity. Clearly, due to the noise, such an equation cannot have a solution, and a reflection measure should be added to the equation. Thus the right stochastic

equation to study is:

$$\begin{cases} \partial_t X = -\frac{1}{2}\Delta(\Delta X + f(X) + \eta) + \partial_\theta \dot{W}, & \text{with } \theta \in [0, 1] = \Omega, \\ \nabla X \cdot \nu = 0 = \nabla(\Delta X) \cdot \nu, & \text{on } \partial\Omega, \end{cases} \quad (0.3)$$

where f is defined below, and where the measure is subject to the contact condition almost surely:

$$\int X d\eta = 0. \quad (0.4)$$

Stochastic partial differential equations with reflection can model the described problem or the evolution of random interfaces near a hard wall (see [21] and [38]). For other results on fluctuations of random interfaces, see [22]. For a detailed study of the contact set $\{(t, \theta) : X(t, \theta) = 0\}$ and of the reflection measure η , see [14], [36] and [37]. The equation (0.3) has been studied when no nonlinear term is taken into account in [16]. In this paper, the authors have introduced various techniques needed to overcome the lack of comparison principle for fourth order equations. Indeed, the case of a second order equation was studied in [31] where an extensive use of monotonicity is used, as well as in all the articles treating with the second order case.

This article is in the spirit of [37] where a nonlinear term is taken into account for the second order equation. We study existence and uniqueness of solution for equation (0.3) with f of the form:

$$f(x) := f_{\ln}(x) := \begin{cases} -\ln x, & \text{for all } x > 0 \\ +\infty, & \text{for all } x \leq 0, \end{cases} \quad (0.5)$$

or for $\alpha > 0$:

$$f(x) := f_\alpha(x) := \begin{cases} x^{-\alpha}, & \text{for all } x > 0 \\ +\infty, & \text{for all } x \leq 0. \end{cases} \quad (0.6)$$

Moreover we characterize the case when the measure η vanishes. Our method mixes ideas from [16] and [37]. Additional difficulties are overcome, the main one being to understand how to deal with the nonlinear term. Again in [37], this term is not difficult to consider thanks to monotonicity arguments.

Our main results state that equations (0.3), (0.4) together with an initial condition have a unique solution (see 2.1 and 2.2). It is constructed thanks to the gradient structure of (0.3) and Strong Feller property. Furthermore, we prove that the measure η vanishes only for f described in (0.6) with $\alpha \geq 3$ (see 3.4).

1 Preliminaries

1.1 Notation

We denote by $\langle \cdot, \cdot \rangle$ the scalar product in $L^2(0, 1)$:

$$\text{for all } h, k \in L^2(0, 1) \quad \langle h, k \rangle = \int_0^1 h(\theta)k(\theta)d\theta.$$

We denote by A the realization in $L^2(0, 1)$ of the Laplace operator with Neumann boundary condition, i.e.:

$$D(A) = \text{Domain of } A = \{h \in W^{2,2}(0, 1) : h'(0) = h'(1) = 0\}$$

where the space $W^{2,2}(0, 1)$ is the classical Sobolev space. Below we use the notation $W^{n,p}$ and $\|\cdot\|_{W^{n,p}}$ to denote the Sobolev space $W^{n,p}(0, 1)$ and its associated norm. Remark that A is self-adjoint on $L^2(0, 1)$ and we have a complete orthonormal system of eigenvectors $(e_i)_{i \in \mathbb{N}}$ in $L^2(0, 1)$ associated to the eigenvalues $\lambda_i := -(i\pi)^2$ where we define:

$$e_0(\theta) = 1, \quad e_i(\theta) = \sqrt{2} \cos(i\pi\theta), \quad \text{for all } i \in \mathbb{N}^*, \quad \text{for all } \theta \in [0, 1].$$

We denote by \bar{h} the mean of $h \in L^2(0, 1)$:

$$\bar{h} = \int_0^1 h(\theta)d\theta = \langle h, e_0 \rangle.$$

Then we define for all $c \in \mathbb{R}$:

$$L_c^2 = \{h \in L^2(0, 1) : \bar{h} = c\},$$

and $L^2 = L^2(0, 1)$. We remark that $(-A)^{-1} : L_0^2 \rightarrow L_0^2$ is well defined. We denote by Q this operator. We can extend the definition of Q to $L^2(0, 1)$ (we denote this operator \bar{Q}) by the formula:

$$\bar{Q}h = Q(h - \bar{h}) + \bar{h}, \quad \text{for all } h \in L^2(0, 1)$$

For $\gamma \in \mathbb{R}$, we define $(-A)^\gamma$ by setting

$$(-A)^\gamma h = \sum_{i=1}^{+\infty} (-\lambda_i)^\gamma h_i e_i, \quad \text{when } h = \sum_{i=0}^{+\infty} h_i e_i.$$

The domain of $(-A)^{\gamma/2}$ is

$$V_\gamma := D((-A)^{\gamma/2}) = \left\{ h = \sum_{i=0}^{+\infty} h_i e_i : \sum_{i=1}^{+\infty} (-\lambda_i)^\gamma h_i^2 < +\infty \right\}.$$

It is endowed with the seminorm

$$|h|_\gamma = \left(\sum_{i=1}^{+\infty} (-\lambda_i)^\gamma h_i^2 \right)^{1/2},$$

and with the norm

$$\|h\|_\gamma = (|h|_\gamma^2 + \bar{h}^2)^{1/2},$$

associated to the scalar product defined for all $h, k \in V_\gamma$ by $(h, k)_\gamma$.

For $\gamma = -1$, $V_{-1} = D((-A)^{-1/2})$ is the completion of the space of functions $h \in L^2$ such that

$$\begin{aligned} \langle \bar{Q}h, h \rangle &= \langle Q(h - \bar{h}) + \bar{h}, h \rangle &= \langle (-A)^{-1}(h - \bar{h}), h - \bar{h} \rangle + \bar{h}^2 \\ &= \langle (-A)^{-1/2}(h - \bar{h}), (-A)^{-1/2}(h - \bar{h}) \rangle \\ &= |h|_{-1}^2 + \bar{h}^2 < +\infty. \end{aligned}$$

To lighten notations, we set $(\cdot, \cdot) := (\cdot, \cdot)_{-1}$ for the inner product of V_{-1} . The average plays an important role and we often work with functions with a fixed average $c \in \mathbb{R}$. We define $H_c = \{h \in H, \bar{h} = c\}$ for all $c \in \mathbb{R}$. We set

$$D(B) = W_0^{1,2}(0,1), B = \frac{\partial}{\partial \theta}, D(B^*) = W^{1,2}(0,1) \text{ and } B^* = -\frac{\partial}{\partial \theta}.$$

We remark that $BB^* = -A$. Finally, we denote by Π the orthogonal projector of V_{-1} onto H_0 . We have:

$$\begin{aligned} \Pi : V_{-1} &\rightarrow H_0 \\ h &\mapsto h - \bar{h}. \end{aligned}$$

Notice that Π is also an orthogonal projector of L^2 onto L_0^2 . Moreover:

$$-A\bar{Q}h = \Pi h, \text{ for all } h \in L^2(0,1). \quad (1.1)$$

We denote by $\mathcal{B}_b(H_c)$ the space of all Borel bounded functions and $\mathcal{C}_b(H_c)$ the space of continuous bounded functions. We set $O_{s,t} := [s, t] \times [0, 1]$ for $s, t \in [0, T]$ with $s < t$ and $T > 0$, and $O_t = O_{0,t}$ for $0 \leq t \leq T$. Given a measure ζ on $O_{s,t}$ and a continuous function v on $O_{s,t}$, we set

$$\langle v, \zeta \rangle_{O_{s,t}} := \int_{O_{s,t}} v d\zeta.$$

In order to solve the equation (0.3), we use a Lipschitz approximation of this equation. We denote by $\{f^n\}_{n \in \mathbb{N}}$ the sequence of Lipschitz functions which converges to the function f on $(0, +\infty)$, defined for $n \in \mathbb{N}$ by:

$$f^n(x) := f(x^+ + 1/n), \text{ for all } x \in \mathbb{R}.$$

When $f = f_{\ln}$ is the logarithmic function (0.5), we use the following positive antiderivative of $-f^n = -f_{\ln}^n$

$$F^n(x) = F_{\ln}^n(x) := (x + 1/n) \ln(x^+ + 1/n) - x^+ + 1 - 1/n, \text{ for all } x \in \mathbb{R},$$

and the following positive antiderivative of $-f = -f_{\ln}$ defined only on \mathbb{R}^+ by:

$$F(x) = F_{\ln}(x) := x \ln(x) - x + 1, \text{ for all } x \in \mathbb{R}^+.$$

When $f = f_\alpha$ is the negative α -power function (0.6) with $\alpha \neq 1$, we use the following antiderivative of $-f^n = -f_\alpha^n$

$$F^n(x) = F_\alpha^n(x) := \frac{(x^+ + 1/n)^{1-\alpha}}{\alpha - 1} + n^\alpha x^-, \text{ for all } x \in \mathbb{R},$$

and the following antiderivative of $-f = -f_\alpha$ defined only on \mathbb{R}^+ by:

$$F(x) = F_\alpha(x) := \frac{x^{1-\alpha}}{\alpha - 1}, \text{ for all } x \in \mathbb{R}^+.$$

Finally when $\alpha = 1$, we use the following antiderivative of $-f^n = -f_\alpha^n$

$$F^n(x) = F_\alpha^n(x) := -\ln(x^+ + 1/n) + nx^-, \text{ for all } x \in \mathbb{R},$$

and the following antiderivative of $-f = -f_\alpha$ defined only on \mathbb{R}^+ by:

$$F(x) = F_\alpha(x) := -\ln x, \text{ for all } x \in \mathbb{R}^+.$$

We use the notation f, f^n, F, F^n when the result holds both for f_{\ln} and f_α . Otherwise we use $f_{\ln}, f_{\ln}^n, F_{\ln}, F_{\ln}^n$ or $f_\alpha, f_\alpha^n, F_\alpha, F_\alpha^n$.

With these notations, we rewrite (0.3) in the abstract form:

$$\begin{cases} dX = -\frac{1}{2}(A^2 X + Af(X))dt + BdW, \\ \langle X, \eta \rangle_{O_T} = 0, \\ X(0, x) = x \text{ for } x \in V_{-1}. \end{cases} \quad (1.2)$$

Finally, in all the article, C denotes a constant which may depend on T and α and its value may change from one line to another.

1.2 The linear equation

The linear equation is given by

$$\begin{cases} dZ(t, x) = -\frac{1}{2}A^2Z(t, x)dt + BdW, & \text{for all } t \in [0, T], \\ Z(0, x) = x. \end{cases}$$

where $x \in V_{-1}$. We have

$$Z(t, x) = e^{-tA^2/2}x + \int_0^t e^{-(t-s)A^2/2}BdW_s.$$

As easily seen this process is in $\mathcal{C}([0, +\infty[; L^2(0, 1))$ (see [13]). In particular, the mean of Z is constant and the law of the process $Z(t, x)$ is the Gaussian measure:

$$Z(t, x) \sim \mathcal{N}(e^{-tA^2/2}x, Q_t),$$

where

$$Q_t = \int_0^t e^{-sA^2/2}BB^*e^{-sA^2/2}ds = (-A)^{-1}(I - e^{-tA^2}).$$

□

If we let $t \rightarrow +\infty$, the law of $Z(t, x)$ converges to the Gaussian measure on L^2 :

$$\mu_c := \mathcal{N}(ce_0, Q), \text{ where } c = \bar{x}.$$

Notice that the kernel of Q is $\{te_0, t \in \mathbb{R}\}$ and μ_c is concentrated on L_c^2 . It is important to remark that the measure μ_c is linked to the Brownian motion. Indeed, let $(\mathbf{B}_\theta)_{\theta \in [0, 1]}$ be a Brownian motion, then the law of $Y_c(\theta) = \mathbf{B}(\theta) - \bar{\mathbf{B}} + c$ is μ_c (see [16]).

1.3 Lipschitz Approximation

For $n \in \mathbb{N}$, we study for the following Lipschitz approximation of (1.2) with an initial condition $x \in V_{-1}$:

$$\begin{cases} dX^n + \frac{1}{2}(A^2X^n + Af^n(X^n))dt = BdW, \\ X^n(0, x) = x. \end{cases} \quad (1.3)$$

We prove existence and uniqueness of solution in a suitable space for the equation (1.3). We then follow standard arguments to show existence and uniqueness of an invariant measure for the equation (1.3) with fixed $n \in \mathbb{N}$, and the strong Feller property of the semigroup. First we have to define the definition of a weak solution to (1.3).

We say X^n is a mild solution of (1.3) if it is satisfied for all $t \geq 0$:

$$X^n(t, x) = Z(t, x) - \int_0^t Ae^{-(t-s)A^2/2}f^n(X^n(s, x))ds. \quad (1.4)$$

Lemma 1.1 *Fix $n \in \mathbb{N}$, $0 < \varepsilon < 2/3$ and $p = 4(1 - \varepsilon)$. For all $x \in L^2(0, 1)$ there exists a unique adapted process $X^n \in \mathcal{C}([0, T]; V_{-1}) \cap L^p([0, T]; L^2(0, 1))$ solution of equation (1.4). Moreover for all $t \geq 0$:*

$$\langle X^n(t, x), e_0 \rangle = \langle x, e_0 \rangle. \quad (1.5)$$

Proof : The proof is classical and left to the reader. It is based on the following inequalities

$$\|(-A)^{1/2}e^{-tA^2/2}h\|_0 \leq C\|h\|_0t^{-1/4}, \quad t > 0, \quad h \in L^2 \quad (1.6)$$

$$\|Ae^{-tA^2/2}h\|_0 \leq C\|h\|_0t^{-1/2}, \quad t > 0, \quad h \in L^2 \quad (1.7)$$

$$\|e^{-tA^2/2}h\|_0 \leq C\|h\|_{-1}t^{-1/4}, \quad t > 0, \quad h \in L^2. \quad (1.8)$$

□

It is also standard to prove

Lemma 1.2 For $n \in \mathbb{N}$ and $c \in \mathbb{R}$, for all $t > 0$:

$$|X^n(t, x) - X^n(t, y)|_{-1} \leq \exp(-t\pi^4/2)|x - y|_{-1}, \quad \text{for all } x, y \in L_c^2. \quad (1.9)$$

Proof : We consider for $N \in \mathbb{N}$ and $x, y \in L_c^2$ the process :

$$S^N(t, x, y) = \sum_{i=0}^N \langle X^n(t, x) - X^n(t, y), e_i \rangle e_i, \quad \text{for all } t \geq 0.$$

then $t \mapsto S^N(t, x, y)$ is \mathcal{C}^1 with values in a $(N + 1)$ -dimensional subspace of $D(A)$ such that $\Pi S^N = S^N$. Indeed

$$\begin{aligned} \Pi S^N(t, x, y) &= \sum_{i=1}^N \langle X^n(t, x) - X^n(t, y), e_i \rangle \Pi e_i + \langle X^n(t, x) - X^n(t, y), e_0 \rangle \Pi e_0 \\ &= \sum_{i=1}^N \langle X^n(t, x) - X^n(t, y), e_i \rangle e_i \\ &= S^N - \langle X^n(t, x) - X^n(t, y), e_0 \rangle e_0. \end{aligned}$$

And by (1.5) and since x and y are in L_c^2

$$\langle X^n(t, x) - X^n(t, y), e_0 \rangle = \langle x - y, e_0 \rangle = 0.$$

By (1.1) we have $-A\bar{Q}h = \Pi h$ for all $h \in L^2(0, 1)$, then $-A\bar{Q}S^N = S^N$. Using the spectral behavior of A given in section 1, we have the following computation:

$$\begin{aligned} \frac{d}{dt} |S^N(t, x, y)|_{-1}^2 &= \frac{d}{dt} \langle \bar{Q}S^N(t, x, y), S^N(t, x, y) \rangle \\ &= 2 \langle \frac{d}{dt} S^N(t, x, y), \bar{Q}S^N(t, x, y) \rangle \\ &= \langle -A^2 S^N(t, x, y), \bar{Q}S^N(t, x, y) \rangle \\ &\quad + \langle -A(f^n(X^n(t, x)) - f^n(X^n(t, y))), \bar{Q}S^N(t, x, y) \rangle \\ &= \langle AS^N(t, x, y), S^N(t, x, y) \rangle \\ &\quad + \langle f^n(X^n(t, x)) - f^n(X^n(t, y)), S^N(t, x, y) \rangle \\ &\leq -\pi^4 |S^N(t, x, y)|_{-1}^2 \\ &\quad + \langle f^n(X^n(t, x)) - f^n(X^n(t, y)), S^N(t, x, y) \rangle \end{aligned}$$

This differential inequality implies :

$$|S^N(t, x, y)|_{-1}^2 \leq e^{-t\pi^4} |x - y|_{-1}^2 + \int_0^t e^{-(t-s)\pi^4} \langle f^n(X^n(s, x)) - f^n(X^n(s, y)), S^N(s, x, y) \rangle ds.$$

Moreover by letting $N \rightarrow +\infty$ we have $|S^N(t, x, y)|_{-1}^2 \rightarrow |X^n(t, x) - X^n(t, y)|_{-1}^2$, and since f^n is monotone non-increasing we obtain

$$\begin{aligned} &\langle f^n(X^n(s, x)) - f^n(X^n(s, y)), S^N(s, x, y) \rangle \\ &\xrightarrow{N \rightarrow +\infty} \langle f^n(X^n(s, x)) - f^n(X^n(s, y)), X^n(s, x) - X^n(s, y) \rangle \leq 0. \end{aligned}$$

Then the limit of the integral is nonpositive, and we obtain the expected inequality (1.9).

□

It is classical that $X^n \in \mathcal{C}([0, T]; V_{-1}) \cap L^p([0, T]; L^2(0, 1))$ satisfies (1.4) if and only if it is a weak solution of (1.3) in the sense

Definition 1.1 For $n \in \mathbb{N}$, $0 < \varepsilon < 2/3$ and $p = 4(1 - \varepsilon)$, let $x \in \mathcal{C}([0, 1], \mathbb{R}^+)$ with $\bar{x} > 0$. We say that $(X^n(t, x))_{t \in [0, T]}$, defined on a stochastic basis linked to $(W(t))_{t \in [0, T]}$, is a solution to (1.3) on $[0, T]$ if :

- (a) almost surely $X^n(\cdot, x) \in \mathcal{C}([0, T]; V_{-1}) \cap L^p([0, T]; L^2(0, 1))$,
- (b) for all $h \in D(A^2)$ and for all $0 \leq t \leq T$:

$$\begin{aligned} \langle X^n(t, x), h \rangle &= \langle x, h \rangle - \int_0^t \langle X^n(s, x), A^2 h \rangle ds \\ &\quad - \int_0^t \langle Ah, f^n(X^n(s, x)) \rangle ds - \int_0^t \langle Bh, dW \rangle. \end{aligned}$$

We now describe an important property of equation (1.3). It can be described as a gradient system in V_{-1} with a convex potential, and can be rewritten as:

$$\begin{cases} dX^n - \frac{1}{2}A(-AX^n + \nabla U^n(X^n))dt = BdW, \\ X^n(0, x) = x \in L^2(0, 1), \end{cases} \quad (1.10)$$

where ∇ denotes the gradient in the Hilbert space $L^2(0, 1)$, and :

$$U^n(x) := \int_0^1 F^n(x(\theta))d\theta, \quad x \in L^2(0, 1). \quad (1.11)$$

Notice that $\nabla U^n(x) = -f^n(x)$ which is dissipative, then U^n is a convex potential. Finally, we define the probability measure on L_c^2 :

$$\nu_c^n(dx) = \frac{1}{Z_c^n} \exp(-U^n(x)) \mu_c(dx), \quad (1.12)$$

where Z_c^n is a normalization constant. By Lemma 1.2, we easily obtain that the equation (1.3) in H_c has a unique ergodic invariant measure and it is not difficult to prove that this measure is precisely ν_c^n . Since the potential U^n is convex, we can prove that the transition semigroup is strong Feller. Let $(P_t^{n,c})_{n \in \mathbb{N}}$ be the sequence of transition semigroup for an initial condition in H_c such that

$$P_t^{n,c} \phi(x) = \mathbb{E}[\phi(X^{n,c}(t, x))], \quad \text{for all } t \geq 0, x \in H_c, \phi \in \mathcal{B}_b(H_c) \text{ and } n \in \mathbb{N}^*,$$

where $X^{n,c}(t, x)$ is the solution of the equation (1.10).

Proposition 1.1 For arbitrary $T > 0$, there exists a constant $C_T > 0$ such that for all $\phi \in \mathcal{B}_b(H_c)$, for all $n \in \mathbb{N}$ and for all $t \in [0, T]$:

$$|P_t^{n,c} \phi(x) - P_t^{n,c} \phi(y)| \leq \frac{\sqrt{C_T}}{\sqrt{t}} \|\phi\|_\infty \|x - y\|_{-1}, \quad \text{for all } x, y \in H_c. \quad (1.13)$$

Proof : We now consider the following process :

$$\begin{aligned} H_0 &\rightarrow H_0 \\ x &\mapsto \mathcal{X}^{n,c}(t, x) = X^n(t, x + ce_0) - ce_0 \end{aligned}$$

which solves the following equation :

$$\begin{cases} d\mathcal{X}^{n,c} - \frac{1}{2}A(-A\mathcal{X}^{n,c} + \nabla U^n(ce_0 + \mathcal{X}^{n,c}))dt = BdW, \\ \mathcal{X}^{n,c}(0, x) = x \in H_0. \end{cases} \quad (1.14)$$

This equation describes a gradient system in H_0 with non-degenerate noise and with a convex potential. We fix $c > 0$ and $n \in \mathbb{N}$, and denote $\mathcal{P}_t^{n,c}$ the markov transition semigroup defined by :

$$\mathcal{P}_t^{n,c}\psi(x) = \mathbb{E}[\psi(\mathcal{X}^{n,c}(t, x))], \quad \text{for all } t \geq 0, \text{ for all } x \in H_0, \text{ for all } \psi \in \mathbf{B}_b(H_0).$$

For all $c \in \mathbb{R}$, for all $x \in H_c$ and $\psi \in \mathcal{B}_b(H_0)$, if we set

$$\begin{aligned} \phi : H_c &\rightarrow \mathbb{R} \\ u &\mapsto \psi(u - ce_0), \end{aligned}$$

we have the following equality:

$$\mathcal{P}_t^{n,c}\psi(x - ce_0) = P_t^{n,c}\phi(x). \quad (1.15)$$

Then for all $c \in \mathbb{R}$, for all $x \in H_c$ and $\psi \in \mathcal{B}_b(H_0)$, the following Bismut-Elworthy formula holds:

$$D\mathcal{P}_t^{n,c}\psi(x - ce_0) \cdot h = \frac{1}{t} \mathbb{E} \left[\psi(\mathcal{X}^{n,c}(t, x - ce_0)) \int_0^t \langle D\mathcal{X}^{n,c}(s, x - ce_0) \cdot h, dW \rangle \right]. \quad (1.16)$$

Then by (1.14) and (1.16),

$$|DP_t^{n,c}\phi(x) \cdot h|^2 \leq \frac{1}{t^2} \|\phi\|_\infty^2 \mathbb{E} \left[\int_0^t \|DX^{n,c}(s, x) \cdot h\|_{-1}^2 ds \right]. \quad (1.17)$$

Let x and y be arbitrary elements in H_c , then by the mean value theorem, for $\sigma(y) \in [0, T]$

$$P_t^{n,c}\phi(x) - P_t^{n,c}\phi(y) = DP_t^{n,c}\phi(x + \sigma(y)(x - y)) \cdot (x - y). \quad (1.18)$$

We use an estimate on $\|DX^{n,c}(s, x + \sigma(y)(x - y)) \cdot (x - y)\|_{-1}^2$, (1.17) and (1.18), and we have the expected result for all $x, y \in H_c$

$$|P_t^{n,c}\phi(x) - P_t^{n,c}\phi(y)| \leq \frac{\sqrt{C_T}}{\sqrt{t}} \|\phi\|_\infty \|x - y\|_H.$$

□

As usual some computations below are formal and would be difficult to justify rigourously in our infinite dimensionnal setting. However the final result is easy to justify by Galerkin approximation (see [12], section 3.2).

2 Solutions of equation with a reflection measure

For all $n \in \mathbb{N}$ we have a unique solution X^n of (1.3). We want to know if these solutions converge to a solution of the equation (0.3). First we describe the definition of a weak solution for (0.3) :

Definition 2.1 *Let $x \in \mathcal{C}([0, 1], \mathbb{R}^+)$ and $\bar{x} > 0$. We say that $((X(t, x))_{t \in [0, T]}, \eta, W)$, defined on a filtered complete probability space $(\Omega, \mathbb{P}, \mathcal{F}, (\mathcal{F}_t)_{t \in [0, T]})$, is a weak solution to (0.3) on $[0, T]$ for the initial condition x if:*

- (a) *a.s. $X \in \mathcal{C}([0, T] \times [0, 1]; \mathbb{R}^+) \cap \mathcal{C}([0, T]; V_{-1})$ and $X(0, x) = x$,*
- (b) *a.s. η is a positive measure on $(0, T] \times [0, 1]$, such that $\eta(O_{\delta, T}) < +\infty$ for all $\delta \in (0, T]$,*
- (c) *W is a cylindrical Wiener process on $L^2(0, 1)$,*
- (d) *the process $(X(\cdot, x), W)$ is (\mathcal{F}_t) -adapted,*
- (e) *a.s. $f(X(\cdot, x)) \in L^1(O_T)$,*
- (f) *for all $h \in D(A^2)$ and for all $0 < \delta \leq t \leq T$:*

$$\begin{aligned} \langle X(t, x), h \rangle &= \langle X(\delta, x), h \rangle - \int_{\delta}^t \langle X(s, x), A^2 h \rangle ds - \int_{\delta}^t \langle Ah(\theta), f(X(s, x)) \rangle ds \\ &\quad - \langle Ah, \eta \rangle_{O_{\delta, t}} - \int_{\delta}^t \langle Bh, dW \rangle, \quad \text{a.s.}, \end{aligned}$$

- (g) *a.s. the contact property holds : $\text{supp}(\eta) \subset \{(t, \theta) \in O_T / X(t, x)(\theta) = 0\}$, that is,*

$$\langle X, \eta \rangle_{O_T} = 0.$$

Finally, a weak solution (X, η, W) is a strong solution if the process $t \mapsto X(t, x)$ is adapted to the filtration $t \mapsto \sigma(W(s, \cdot), s \in [0, t])$

Remark 2.1 *In (f), the only term where we use the function f is well defined. Indeed, by (e) we have $f(X(\cdot, x)) \in L^1(O_T)$ and by Sobolev embedding $Ah \in D(A) \subset L^\infty(O_T)$. Hence the notation $\langle \cdot, \cdot \rangle$ should be interpreted as a duality between L^∞ and L^1 .*

2.1 Pathwise uniqueness

We want to prove that for any pair $(X^i, \eta^i, W), i = 1, 2$, of weak solutions of (0.3) defined on the same probability space with the same driving noise W and with $X_0^1 = X_0^2$, we have $(X^1, \eta^1) = (X^2, \eta^2)$. This pathwise uniqueness will be used in the next subsection to construct stationary strong solutions of (0.3).

Proposition 2.1 *Let $x \in \mathcal{C}([0, 1], \mathbb{R}^+)$ with $\bar{x} > 0$. Let $(X^i, \eta^i, W), i = 1, 2$ be two weak solutions of (0.3) with $X_0^1 = x = X_0^2$. Then $(X^1, \eta^1) = (X^2, \eta^2)$.*

Proof : We use the following Lemma from [16]. For the sake of completeness, we recall the proof.

Lemma 2.1 *Let ζ be a finite signed measure on $O_{\delta, T}$, $V \in \mathcal{C}(O_{\delta, T})$ and $c > 0$. Suppose that:*

- i) for all $r \in [\delta, T]$, for all $h \in \mathcal{C}([0, 1])$, such that $\bar{h} = 0$, $\langle h, \zeta \rangle_{O_{r, T}} = 0$,*
- ii) for all $r \in [\delta, T]$, $\overline{V(r, \cdot)} = c$ with $\langle V, \zeta \rangle_{O_{r, T}} = 0$,*

then ζ is the null measure.

Proof : Let $k \in \mathcal{C}([0, 1])$. Since ζ is a finite measure, by *i*) we obtain for all $\delta \leq s \leq t \leq T$:

$$\langle k, \zeta \rangle_{O_{s,t}} = \langle \bar{k}, \zeta \rangle_{O_{s,t}} = \bar{k} \zeta(O_{s,t}), \quad \text{for all } k \in \mathcal{C}([0, 1]).$$

This implies ζ can be decomposed as $\zeta = \gamma \otimes d\theta$, where γ is a measure on $[0, T]$. By *ii*), we obtain:

$$0 = \langle V, \zeta \rangle_{O_{s,t}} = \int_s^t \left(\int_0^1 V(s, \theta) d\theta \right) d\gamma = c\gamma([s, t]).$$

We conclude that for all $\delta \leq s \leq t \leq T$, $\gamma([s, t]) = 0$, since $c > 0$. Thus ζ is the null measure. \square

We now prove the proposition. Let $Y(t) = X^1(t, x) - X^2(t, x)$ and $\zeta = \eta^1 - \eta^2$, Y is the solution of the following equation:

$$\begin{cases} dY = -\frac{1}{2} (A^2 Y + A(f(X^1) - f(X^2))) dt, \\ Y(0) = 0. \end{cases} \quad (2.1)$$

We consider now the following approximation of Y :

$$Y^N(t, \cdot) = \frac{1}{N} \sum_{n=0}^N \sum_{i=0}^n \langle Y(t), e_i \rangle e_i.$$

Since Y is continous, then Y^N converges uniformly to Y on O_T . Notice that for all $i \geq 0$, the process $t \mapsto \langle Y(t), e_i \rangle$ has bounded variation, and in particular the process $t \mapsto Y^N(t)$ has bounded variation as process with values in a finite-dimensional subspace of $D(A)$. Taking the scalar product in V_{-1} between Y and Y^N , we obtain:

$$\begin{cases} d(Y, Y^N) = 2(Y^N, dY) = - (Y^N, A^2 Y + A(f(X^1) - f(X^2)) + A\zeta) dt, \\ (Y, Y^N)(0) = 0. \end{cases} \quad (2.2)$$

Moreover for all $t \geq 0$, $\langle Y(t), e_0 \rangle = 0$, so $\Pi Y^N(t) = Y^N(t)$. So we have for all $0 < \delta \leq t \leq T$:

$$\begin{aligned} (Y(t), Y^N(t)) &= (Y(\delta), Y^N(\delta)) + \int_\delta^t \langle AY^N(s), Y(s) \rangle ds \\ &\quad + \int_\delta^t \langle Y^N(s), f(X^1(s, x)) - f(X^2(s, x)) \rangle ds + \langle Y^N(s), \zeta \rangle_{O_{\delta,t}} \\ &= (Y(\delta), Y^N(\delta)) - \frac{1}{N} \sum_{n=0}^N \sum_{i=0}^n (i\pi)^2 \int_\delta^t \langle Y(s), e_i \rangle^2 ds + \langle Y^N(s), \zeta \rangle_{O_{\delta,t}} \\ &\quad + \frac{1}{N} \sum_{n=0}^N \sum_{i=0}^n \int_\delta^t \langle Y(s, \cdot), e_i \rangle \langle f(X^1(s, x)) - f(X^2(s, x)), e_i \rangle ds \\ &\leq (Y(\delta), Y^N(\delta)) + \langle Y^N(s), \zeta \rangle_{O_{\delta,t}} \\ &\quad + \frac{1}{N} \sum_{n=0}^N \sum_{i=0}^n \int_\delta^t \langle Y(s, \cdot), e_i \rangle \langle f(X^1(s, x)) - f(X^2(s, x)), e_i \rangle ds. \end{aligned} \quad (2.3)$$

For all $s \in [\delta, t]$,

$$\begin{aligned} &\frac{1}{N} \sum_{n=0}^N \sum_{i=0}^n \langle Y(s), e_i \rangle \langle f(X^1(s, x)) - f(X^2(s, x)), e_i \rangle - \langle Y(s), f(X^1(s, x)) - f(X^2(s, x)) \rangle \\ &= \left\langle \frac{1}{N} \sum_{n=0}^N \sum_{i=0}^n \langle Y(s), e_i \rangle e_i - Y(s), f(X^1(s, x)) - f(X^2(s, x)) \right\rangle \\ &= \langle Y^N(s) - Y(s), f(X^1(s, x)) - f(X^2(s, x)) \rangle \\ &\leq \|Y^N(s) - Y(s)\|_{L^\infty([0,1])} \|f(X^1(s, x)) - f(X^2(s, x))\|_{L^1([0,1])}, \end{aligned}$$

where $\|\cdot\|_{L^\infty([0,1])}$ and $\|\cdot\|_{L^1([0,1])}$ are the classical norm on the space $[0,1]$. The latter term converges to zero since $Y^N(s)$ converges uniformly to $Y(s)$ on $[0,1]$. Taking the negative part, we have by Fatou's lemma:

$$\begin{aligned}
& \liminf_{N \rightarrow +\infty} \int_\delta^t \left(\frac{1}{N} \sum_{n=0}^N \sum_{i=0}^n \langle Y(s), e_i \rangle \langle f(X^1(s, x)) - f(X^2(s, x)), e_i \rangle \right)^- ds \\
& \geq \int_\delta^t \liminf_{N \rightarrow +\infty} \left(\frac{1}{N} \sum_{n=0}^N \sum_{i=0}^n \langle Y(s), e_i \rangle \langle f(X^1(s, x)) - f(X^2(s, x)), e_i \rangle \right)^- ds \\
& = \int_\delta^t (\langle Y(s), f(X^1(s, x)) - f(X^2(s, x)) \rangle)^- ds \\
& = 0,
\end{aligned}$$

since f is nonincreasing. Taking the limit in (2.3) as N grows to infinity, we obtain by the contact condition

$$\begin{aligned}
\|Y(t)\|_{-1}^2 - \|Y(\delta)\|_{-1}^2 & \leq \langle Y, \zeta \rangle_{O_{\delta,t}} \\
& = -\langle X^1, \eta^2 \rangle_{O_{\delta,t}} - \langle X^2, \eta^1 \rangle_{O_{\delta,t}} \\
& \leq 0.
\end{aligned}$$

Letting $\delta \rightarrow 0$, we have $Y(t) = 0$ for all $t \geq 0$ and $X^1(t, x) = X^2(t, x)$ for all $t \geq 0$. Moreover, with the definition of a weak solution, we see that :

$$\text{for all } h \in D(A^2), \quad \langle Ah, \zeta \rangle_{O_{\delta,t}} = 0.$$

By density, we obtain ζ and $V = X^1 = X^2$ satisfy the hypothesis of Lemma 2.1, and therefore ζ is the null measure, i.e. $\eta^1 = \eta^2$.

□

2.2 Convergence of invariants measures

Let :

$$K = \{x \in L^2(0, 1), x \geq 0\},$$

then we know that μ_c is the law of $Y^c = \mathbf{B} - \overline{\mathbf{B}} + c$. We remark the following inclusion :

$$\{\mathbf{B}_\theta \in [-c/2, c/2], \text{ for all } \theta \in [0, 1]\} \subset \{Y^c \in K\},$$

therefore $\mu_c(K) > 0$ with $c > 0$. Let us define U the potential associated to the function f . If $f = f_{\ln}$ is the logarithmic function, U is defined by:

$$U(x) = U_{\ln}(x) := \begin{cases} \int_0^1 F_{\ln}(x(\theta)) d\theta & \text{if } x \in K, \\ +\infty & \text{else.} \end{cases}$$

If $f = f_\alpha$ is the negative α -power function, U is defined by:

$$U(x) = U_\alpha(x) := \begin{cases} \int_0^1 F_\alpha(x(\theta)) d\theta & \text{if } \int_0^1 |F_\alpha(x(\theta))| d\theta < +\infty \text{ and } x \in K, \\ +\infty & \text{else.} \end{cases}$$

Remark 2.2 Note that, for $\alpha < 1$, $F_\alpha(x(\theta)) = -\frac{1}{1-\alpha} x(\theta)^{1-\alpha}$. By Hölder inequality:

$$\int_0^1 |F_\alpha(x(\theta))| d\theta < +\infty, \text{ for all } x \in K.$$

We have the following result :

Proposition 2.2 For $c > 0$,

$$\nu_c^n \rightarrow \nu_c := \frac{1}{Z_c} \exp^{-U(x)} \mathbb{1}_{x \in K} \mu_c(dx), \text{ when } n \rightarrow +\infty,$$

where Z_c is a normalization constant.

Proof : Let $\psi \in C_b^0(L^2, \mathbb{R})$. We want to prove that

$$\int_H \psi(x) \exp(-U^n(x)) \mu_c(dx) \xrightarrow{n \rightarrow +\infty} \int_H \psi(x) \exp(-U(x)) \mathbb{1}_{x \in K} \mu_c(dx). \quad (2.4)$$

Case 1 $f = f_{\ln}$ is the logarithmic function.

We have that for a fixed $x \in H$,

$$\exp(-U^n(x)) \xrightarrow{n \rightarrow +\infty} \exp(-U(x)) \mathbb{1}_{x \in K}. \quad (2.5)$$

Indeed, for all $x \notin K$ there exists $\delta_x > 0$ small such that $\lambda(\{\theta \in [0, 1] / x(\theta) \leq -\delta_x\}) > 0$ and we have:

$$\int_0^1 F_{\ln}^n(x(\theta)) \mathbb{1}_{\{x < 0\}} d\theta > \int_0^1 F_{\ln}^n(x(\theta)) \mathbb{1}_{\{x \leq -\delta_x\}} d\theta > 0, \quad \text{for all } n \geq 1.$$

Then, since F_{\ln}^n is nonincreasing on $(-\infty, 0)$:

$$\begin{aligned} 0 \leq \exp(-U_{\ln}^n(x)) &\leq \exp\left(-\int_0^1 F_{\ln}^n(x(\theta)) \mathbb{1}_{\{x \leq -\delta_x\}} d\theta\right) \\ &\leq \exp\left(-\int_0^1 F_{\ln}^n(-\delta_x) \mathbb{1}_{\{x \leq -\delta_x\}} d\theta\right) \\ &\leq \exp\left(-F_{\ln}^n(-\delta_x) \lambda(\{x \leq -\delta_x\})\right) \\ &\leq \exp\left(\left((1/n - \delta_x) \ln n - 1 + 1/n\right) \lambda(\{x \leq -\delta_x\})\right). \end{aligned}$$

And this latter term converges to zero as n grows to infinity.

Now for $x \in K$, $F_{\ln}^n(x(\theta))$ converges to $F_{\ln}(x(\theta))$ almost everywhere as n grows to infinity. Moreover $F_{\ln}^n(\tilde{x}(\theta)) \leq \mathbb{1}_{x \leq 1} + F_{\ln}^1(\tilde{x}(\theta)) \mathbb{1}_{x > 1}$, and the right-hand side is clearly integrable. By the dominated convergence Theorem, we deduce (2.5).

Since $U_{\ln}^n \geq 0$, (2.4) follows by dominated convergence Theorem.

Case 2 $f = f_{\alpha}$ is negative α -power function.

For a fixed $x \in L^2$, the potentials are increasing as n grows to infinity, we deduce:

$$\exp(-U_{\alpha}^n(x)) \leq \exp(-U_{\alpha}^1(x)), \quad \text{for all } n \geq 1, \quad \text{for all } x \in L^2. \quad (2.6)$$

The right-hand side is integrable on H , thus it suffices to prove that for a fixed $x \in H$,

$$\exp(-U_{\alpha}^n(x)) \xrightarrow{n \rightarrow +\infty} \exp(-U_{\alpha}(x)) \mathbb{1}_{x \in K}, \quad (2.7)$$

where

$$\exp(-U_{\alpha}(x)) \mathbb{1}_{x \in K} = \begin{cases} \exp(-U_{\alpha}(x)) & \text{if } \int_0^1 |F_{\alpha}(x(\theta))| d\theta < +\infty \text{ and } x \in K, \\ 0 & \text{else.} \end{cases} \quad (2.8)$$

For $x \notin K$, there exists $\delta_x > 0$ small such that $\lambda(\{\theta \in [0, 1] / x(\theta) \leq -\delta_x\}) > 0$ and we have:

$$\text{for all } n \in \mathbb{N}^*, \quad \int_0^1 F_{\alpha}^n(x(\theta)) \mathbb{1}_{\{x < 0\}} d\theta > \int_0^1 F_{\alpha}^n(x(\theta)) \mathbb{1}_{\{x \leq -\delta_x\}} d\theta > 0.$$

Then

$$\begin{aligned}
0 \leq \exp^{-U_\alpha^n(x)} &\leq \exp\left(-\int_0^1 F_\alpha^n(x(\theta)) \mathbf{1}_{\{x \leq -\delta_x\}} d\theta\right) \\
&\leq \exp\left(-\int_0^1 F_\alpha^n(-\delta_x) \mathbf{1}_{\{x \leq -\delta_x\}} d\theta\right) \\
&= \exp(-F_\alpha^n(-\delta_x) \lambda(\{x \leq -\delta_x\})).
\end{aligned}$$

And this latter term converges to zero as n grows to infinity. Thus (2.7) holds.

For $x \in K$, such that $\int_0^1 |F_\alpha(x(\theta))| d\theta < +\infty$, $F_\alpha^n(x(\theta))$ converges almost everywhere to $F_\alpha(x(\theta))$ as n grows to infinity. Moreover $F_\alpha^1(x(\theta)) \leq F_\alpha^n(x(\theta)) \leq F_\alpha(x(\theta))$ for all $\theta \in [0, 1]$, and by the dominated convergence Theorem (2.7) holds.

If $\int_0^1 |F_\alpha(x(\theta))| d\theta = +\infty$, necessarily $\alpha \geq 1$. For $\alpha > 1$, $F_\alpha^n \geq 0$ and (2.7) follows from monotone convergence. If $\alpha = 1$, we write

$$\int_0^1 F_\alpha^n(x(\theta)) d\theta = \int_0^1 F_\alpha^n(x(\theta)) \mathbf{1}_{x(\theta) \leq 1/2} d\theta + \int_0^1 F_\alpha^n(x(\theta)) \mathbf{1}_{x(\theta) > 1/2} d\theta.$$

The first term converges to $\int_0^1 F_\alpha(x(\theta)) \mathbf{1}_{x(\theta) \leq 1/2} d\theta$ by monotone convergence, and the second term converges to $\int_0^1 F_\alpha(x(\theta)) \mathbf{1}_{x(\theta) < 1/2} d\theta$ by uniform integrability. We have proved that (2.7) always holds, (2.4) follows. □

2.3 Existence of stationary solutions

In this section, we prove the existence of stationary solutions of equation (0.3) and that they are limits of stationary solutions of (1.3), in some suitable sense. Fix $c > 0$ and consider the unique (in law) stationary solution of (1.3) denote \hat{X}_c^n in H_c . We are going to prove that the laws of \hat{X}_c^n weakly converge as n grows to infinity to a stationary strong solution of (0.3).

Theorem 2.1 *Let $c > 0$ and $T > 0$. Almost surely \hat{X}_c^n converges as n grows to infinity to a process \hat{X}_c in $\mathcal{C}(O_T)$. Moreover $f(\hat{X}_c) \in L^1(O_T)$ almost surely, and setting*

$$d\eta^n = f^n(\hat{X}_c^n(t, \theta)) dt d\theta - f(\hat{X}_c(t, \theta)) dt d\theta,$$

then (\hat{X}_c^n, η^n, W) converges in law to (\hat{X}_c, η, W) stationary strong solution of (0.3).

The proof of 2.1 requires arguments that differ significantly in the logarithmic case and in the negative α -power case. We thus have chosen to do two separated proofs. Some arguments however are similar and are not repeated.

Proof in the logarithmic case:

The proof is splitted in 4 steps. In step 1, assuming that a subsequence of \hat{X}_c^n converges in law. Its limit \hat{X}_c is shown to satisfy $f_{\text{in}}(\hat{X}_c) \in L^1(O_T)$ almost surely. Then in step 2, under the same assumption as in step 1, we prove that up to a further extraction the measures η^n converges to a positive measure η and that (\hat{X}_c, η) is a weak solution in the probabilistic sense. It then remains to prove tightness of \hat{X}_c^n in step 3 and to use pathwise uniqueness to conclude in step 4.

Step 1.

Let us assume that $(n_k)_{k \in \mathbb{N}}$ is a subsequence such that $(\hat{X}_c^{n_k})_{k \in \mathbb{N}}$ converges in law in $\mathcal{C}(O_T)$ to a process \hat{X}_c .

By Skorohod's theorem, we can find a probability space and a sequence of processes $(V^k, \mathcal{W}^k)_{k \in \mathbb{N}}$ on that probability space such that $(V^k, \mathcal{W}^k) \rightarrow (V, \mathcal{W})$ in $\mathcal{C}(O_T)$ almost surely and (V^k, \mathcal{W}^k) has the same distribution as $(\hat{X}_c^{n_k}, \mathcal{W})$ for all $k \in \mathbb{N}$. Notice that $V \geq 0$ almost surely since for all

$t \leq T$ the law of $V(t, \cdot)$ is ν_c which is concentrated on K . Let now ξ^k and ρ^k be the following measures on O_T :

$$d\xi^k := f_{\ln}^{n_k}(V^k(t, \theta)) \mathbb{1}_{V^k < 1} dt d\theta,$$

and

$$d\rho^k := f_{\ln}^{n_k}(V^k(t, \theta)) \mathbb{1}_{V^k \geq 1} dt d\theta.$$

Let $y \in D(A)$ with $\bar{y} = 0$, taking $h \in D(A^2)$ such that $y = Ah$ as a test function in (b) of Definition 1.1, we deduce that, for all $0 \leq t \leq T$, $\langle y, \xi^k + \rho^k \rangle_{O_t}$ has a limit when $n \rightarrow +\infty$. Moreover by the uniform convergence in $\mathcal{C}(O_T)$ of V^k to V , we have

$$f_{\ln}^{n_k}(V^k(t, \theta)) \mathbb{1}_{V^k \geq 1} \xrightarrow{k \rightarrow +\infty} f_{\ln}(V(t, \theta)) \mathbb{1}_{V \geq 1}, \quad \text{for all } (t, \theta) \in O_T, \quad (2.9)$$

and the convergence is uniform. We obtain for all $0 \leq t \leq T$ and for all $h \in D(A)$:

$$\langle h, \rho^k \rangle_{O_t} \xrightarrow{k \rightarrow +\infty} \int_{O_t} h(\theta) f_{\ln}(V(s, \theta)) \mathbb{1}_{V \geq 1} ds d\theta. \quad (2.10)$$

Note that $f_{\ln}(x) \mathbb{1}_{x \geq 1}$ is a continuous function so that $f_{\ln}(V) \mathbb{1}_{V \geq 1} \in L^1(O_T)$. Moreover, for any $y \in D(A)$ with $\bar{y} = 0$, for all $0 \leq t \leq T$,

$$\langle y, \xi^k \rangle_{O_t} \text{ has a limit when } k \rightarrow +\infty. \quad (2.11)$$

Notice that almost surely:

$$f_{\ln}^{n_k}(V^k(t, \theta)) \mathbb{1}_{V^k < 1} \xrightarrow{k \rightarrow +\infty} \begin{cases} +\infty & \text{if } V(t, \theta) \leq 0, \\ f_{\ln}(V(t, \theta)) & \text{if } V(t, \theta) \in (0, 1]. \end{cases} \quad (2.12)$$

Thus the limit of this term is not trivial. Let us now prove that the total mass $\xi^n(O_T)$ is bounded. We use the following Lemma whose proofs is postponed to the end of this section.

Lemma 2.2 *Let $T > 0$, and $\{\mu^k\}_{k \in \mathbb{N}}$ be a sequence of finite positive measures on O_T . Suppose there exists $\{w^k\}_{k \in \mathbb{N}}$ a sequence of functions in $\mathcal{C}(O_T)$ such that w^k converges uniformly to w , when k grows to infinity. Suppose also there exist a function $M_T : \mathcal{C}(O_T) \rightarrow \mathbb{R}^+$ and two nonnegative constants m_T and c_T such that*

$$\text{for all } h \in D(A) \text{ such that } \bar{h} = 0, \quad \langle h, \mu^k \rangle_{O_T} \leq M_T(h), \quad \text{for all } k \in \mathbb{N}, \quad (2.13)$$

$$\text{for all } t \in O_T, \quad \int_0^1 w(t, \theta) d\theta = c_T > 0 \quad (2.14)$$

and

$$\langle w^k, \mu^k \rangle_{O_T} \leq m_T. \quad (2.15)$$

Then there exists a constant \tilde{M}_T such that

$$\text{for all } h \in \mathcal{C}(O_T), \quad \langle h, \mu^k \rangle_{O_T} \leq \tilde{M}_T \|h\|_{\infty}, \quad \text{for all } k \in \mathbb{N}. \quad (2.16)$$

and in particular $\mu^k(O_T)$ is bounded uniformly for $k \in \mathbb{N}$.

Let us denote by :

$$M_T(h) = \sup_{k \in \mathbb{N}} \left| \langle h, \xi^k \rangle_{O_T} \right| \quad (2.17)$$

for $h \in D(A)$ such that $\bar{h} = 0$. By (2.11), we know that M_T is well defined. Moreover we have

$$\langle (V^k)^+, \xi^k \rangle_{O_T} = \int_{O_T} (V^k(t, \theta))^+ f_{\ln}^{n_k}(V^k(t, \theta)) \mathbb{1}_{V^k < 1} dt d\theta. \quad (2.18)$$

Since $(x)^+ f_{\ln}^{n_k}(x) \mathbb{1}_{x < 1}$ is uniformly bounded in $k \in \mathbb{N}$, there exists a positive constant m_T such that

$$\langle (V^k)^+, \xi^k \rangle_{O_T} \leq m_T. \quad (2.19)$$

Since V is almost surely positive, $(V^k)^+$ converges uniformly to V and $\overline{V(t, \cdot)} = c_T > 0$ for all $t \in [0, T]$. We use Lemma 2.2 and obtain $\limsup_{k \rightarrow +\infty} \xi^k(O_T) < +\infty$.

Thanks to Fatou Lemma, we can write :

$$\begin{aligned} \int_{O_T} [f_{\ln}(V(s, \theta)) \mathbb{1}_{V < 1}] ds d\theta &= \int_{O_T} \liminf_{k \rightarrow +\infty} [f_{\ln}^{n_k}(V^k(s, \theta)) \mathbb{1}_{V^k < 1}] ds d\theta \\ &\leq \liminf_{k \rightarrow +\infty} \int_{O_T} [f_{\ln}^{n_k}(V^k(s, \theta)) \mathbb{1}_{V^k < 1}] ds d\theta \\ &< +\infty. \end{aligned} \quad (2.20)$$

It follows that almost surely $f_{\ln}(V) \in L^1(O_T)$. □

Step 2.

We again assume that we have $(n_k)_{k \in \mathbb{N}}$ a subsequence such that $(\hat{X}_c^{n_k})_{k \in \mathbb{N}}$ converges in law to a process \hat{X}_c . Again, by Skorohod's theorem, we can find a probability space and a sequence of processes $(V^k, \mathcal{W}^k)_{k \in \mathbb{N}}$ such that almost surely $(V^k, \mathcal{W}^k) \rightarrow (V, \mathcal{W})$ in $\mathcal{C}(O_T)$ as k grows to infinity, and (V^k, \mathcal{W}^k) has the same distribution as $(\hat{X}_c^{n_k}, W)$ for all $k \in \mathbb{N}$.

By step 1, the total mass $\xi^k(O_T)$ is bounded and there exists $(n_{k_m})_{m \in \mathbb{N}}$ a sub-subsequence such that the measures

$$\xi^{k_m} := f_{\ln}^{n_{k_m}}(V^{k_m}(t, \theta)) \mathbb{1}_{V^{k_m} < 1} dt d\theta$$

converge to a measure ξ .

We denote by λ the following measure:

$$d\lambda := f_{\ln}(V(t, \theta)) \mathbb{1}_{V < 1} dt d\theta, \quad (2.21)$$

and $\zeta^m := \xi^{k_m} - \lambda$. Thus ζ^m converges to the measure $\zeta := \xi - \lambda$. Let u be a continuous nonnegative function on O_T , we have

$$\begin{aligned} \langle u, \zeta \rangle_{O_T} &= \lim_{m \rightarrow +\infty} \langle u, \zeta^m \rangle_{O_T} \\ &= \lim_{m \rightarrow +\infty} \langle u, \xi^{k_m} \rangle_{O_T} - \langle u, \lambda \rangle_{O_T}. \end{aligned}$$

And this is positive, thanks to (2.20). Therefore ζ is a positive measure. Taking the limit as m grows to infinity in the approximated equation, we obtain that for all $h \in D(A^2)$ and for all $0 \leq t \leq T$:

$$\begin{aligned} \langle V(t, \cdot), h \rangle &= \langle x, h \rangle - \int_{O_t} V(s, \theta) A^2 h(\theta) ds d\theta - \int_{O_t} f_{\ln}(V(s, \theta)) A h(\theta) ds d\theta \\ &\quad - \langle A h, \zeta \rangle_{O_t} - \int_0^t \langle B h, d\mathcal{W} \rangle. \end{aligned}$$

This is the expected equation. Let us now show that the contact condition holds for (V, ζ) . We prove in fact that for all β non negative:

$$0 \leq \langle V, \zeta \rangle_{O_T} \leq \beta. \quad (2.22)$$

The key is to study the behavior of $f_{\ln}^{n_{k_m}}(V^{k_m}(t, \theta)) \mathbb{1}_{V^{k_m} < 1}$ near points $(t, \theta) \in O_T$ such that $V(t, \theta)$ is small. Fix $\beta > 0$, there exists $\varepsilon > 0$ such that $-T\varepsilon \ln(\varepsilon) \leq \beta$. Let us define the following measures for all $m \in \mathbb{N}$.

$$\begin{aligned} d\xi_\varepsilon^m &:= f_{\ln}^{n_{k_m}}(V^{k_m}(t, \theta)) \mathbb{1}_{V^{k_m} < \varepsilon} dt d\theta, & d\tau_\varepsilon^m &:= f_{\ln}^{n_{k_m}}(V^{k_m}(t, \theta)) \mathbb{1}_{\varepsilon \leq V^{k_m} < 1} dt d\theta, \\ d\lambda_\varepsilon &:= f_{\ln}(V(t, \theta)) \mathbb{1}_{V < \varepsilon} dt d\theta, & d\tau_\varepsilon &:= f_{\ln}(V(t, \theta)) \mathbb{1}_{\varepsilon \leq V < 1} dt d\theta. \end{aligned}$$

Clearly τ_ε^m converges to τ_ε , it follows

$$\begin{aligned}
\limsup_{m \rightarrow +\infty} \langle V^{k_m}, \zeta^m \rangle_{O_T} &= \limsup_{m \rightarrow +\infty} \left(\langle V^{k_m}, \xi_\varepsilon^{k_m} \rangle_{O_T} - \langle V^{k_m}, \lambda_\varepsilon \rangle_{O_T} + \langle V^{k_m}, \tau_\varepsilon^m \rangle_{O_T} - \langle V^{k_m}, \tau_\varepsilon \rangle_{O_T} \right) \\
&= \limsup_{m \rightarrow +\infty} \left(\int_{O_T} V^{k_m} f_{\ln}^{n_{k_m}}(V^{k_m}) \mathbb{1}_{V^{k_m} < \varepsilon} dt d\theta - \int_{O_T} V^{k_m} f_{\ln}(V) \mathbb{1}_{V < \varepsilon} dt d\theta \right) \\
&\leq \limsup_{m \rightarrow +\infty} \left(\int_{O_T} V^{k_m} f_{\ln}^{n_{k_m}}(V^{k_m}) \mathbb{1}_{0 \leq V^{k_m} < \varepsilon} dt d\theta \right) \\
&\quad + \limsup_{m \rightarrow +\infty} \left(\int_{O_T} (V^{k_m})^- f_{\ln}(V) \mathbb{1}_{V < \varepsilon} dt d\theta \right)
\end{aligned}$$

Since $(V^{k_m})^-$ converges uniformly to zero, we deduce:

$$\begin{aligned}
\limsup_{m \rightarrow +\infty} \langle V^{k_m}, \zeta^m \rangle_{O_T} &\leq T \limsup_{m \rightarrow +\infty} \sup_{x \in [0, \varepsilon]} \left| -x \ln \left(x + \frac{1}{n_{k_m}} \right) \right| \\
&\leq T \limsup_{m \rightarrow +\infty} \left(-\varepsilon \ln \left(\varepsilon + \frac{1}{n_{k_m}} \right) \right) \\
&\leq -T\varepsilon \ln(\varepsilon).
\end{aligned}$$

Thus the contact condition holds. \square

Step 3.

By the convergence of the family $(\nu_c^n)_{n \in \mathbb{N}}$, we know that the initial distribution of \hat{X}_c^n converges to ν_c . We now follow the same argument as in [16], to prove for all $T > 0$, the laws of $(\hat{X}_c^n)_{n \in \mathbb{N}}$ are tight in $\mathcal{C}(O_T)$. Fix $n \geq 1$ and $T > 0$, by the Lyons-Zheng's decomposition (see theorem 5.7.1 in [20]), we can find M^h , respectively N^h , two orthogonal martingales with respect to the natural filtration of $(\hat{X}_c^n(t))_{0 \leq t \leq T}$, respectively the natural filtration of $(\hat{X}_c^n(T-t))_{0 \leq t \leq T}$, such that for all $t \in [0, T]$ and for all $h \in H$:

$$(h, \hat{X}_c^n(t) - \hat{X}_c^n(0)) = \frac{1}{2} M_t^h - \frac{1}{2} (N_T^h - N_{T-t}^h). \quad (2.23)$$

Moreover, the quadratic variations are both equal to $\langle \langle M^h \rangle \rangle_t = \langle \langle N^h \rangle \rangle_t = t \|\Pi h\|_{-1}^2$. Let $u_i = Q^{\gamma-1} e_i$ for all $i \geq 1$. To simplify the notations, we denote M^i and N^i the martingales M^{u_i} and N^{u_i} defined in (2.23). Then we have:

$$\begin{aligned}
\mathbb{E} \left[\left\| \hat{X}_c^n(t) - \hat{X}_c^n(s) \right\|_{-\gamma}^2 \right] &= \mathbb{E} \left[\sum_{i=1}^{+\infty} \left((\hat{X}_c^n(t) - \hat{X}_c^n(s), v_i) \right)_{-\gamma}^2 \right] \\
&= \mathbb{E} \left[\sum_{i=1}^{+\infty} \left((\hat{X}_c^n(t) - \hat{X}_c^n(0), u_i)_{-1} - (\hat{X}_c^n(s) - \hat{X}_c^n(0), u_i)_{-1} \right)^2 \right] \\
&= \frac{1}{4} \mathbb{E} \left[\sum_{i=1}^{+\infty} (M_t^i + N_{T-t}^i - M_s^i - N_{T-s}^i)_{-1}^2 \right] \\
&= \frac{1}{4} \sum_{i=1}^{+\infty} \mathbb{E} [\langle \langle M^i \rangle \rangle_{t-s} + \langle \langle N^i \rangle \rangle_{t-s}] \\
&= \frac{1}{2} \sum_{i=1}^{+\infty} |t-s| \|u_i\|_{-1}^2 \\
&= \frac{|t-s|}{2} \sum_{i=1}^{+\infty} (i\pi)^{2-2\gamma} \\
&\leq \frac{|t-s|}{2} K_{-\gamma}^2,
\end{aligned}$$

where $K_{-\gamma}$ is the Hilbert-Schmidt's norm of inclusion of V_{-1} in $V_{-\gamma}$ which is finite for $\gamma > 3/2$. So we have found a constant $C > 0$ such that for all $t, s \in [0, T]$:

$$\left(\mathbb{E} \left[\left\| \hat{X}_c^n(t) - \hat{X}_c^n(s) \right\|_{-\gamma}^2 \right] \right)^{\frac{1}{2}} \leq C |t - s|^{\frac{1}{2}}. \quad (2.24)$$

Furthermore, for $0 < \delta < 1/2$ and $r \geq 1$, since \hat{X}_c^n is a stationary solution, there exists C such that for all $t, s \in [0, T]$:

$$\begin{aligned} \left(\mathbb{E} \left[\left\| \hat{X}_c^n(t) - \hat{X}_c^n(s) \right\|_{W^{\delta, r}(0,1)}^2 \right] \right)^{\frac{1}{2}} &\leq \left(\mathbb{E} \left[\left\| \hat{X}_c^n(t) \right\|_{W^{\delta, r}(0,1)}^2 \right] \right)^{\frac{1}{2}} + \left(\mathbb{E} \left[\left\| \hat{X}_c^n(s) \right\|_{W^{\delta, r}(0,1)}^2 \right] \right)^{\frac{1}{2}} \\ &\leq 2 \left(\int_H \|y\|_{W^{\delta, r}(0,1)}^2 \nu_c^n(dy) \right)^{\frac{1}{2}} \\ &\leq C \left(\int_H \|y\|_{W^{\delta, r}(0,1)}^2 \mu_c(dy) \right)^{\frac{1}{2}}, \end{aligned} \quad (2.25)$$

since $U^n \geq 0$. And this latter term is finite.

Let $\kappa \in [0, 1]$ and set $\lambda = \kappa\delta - (1 - \kappa)\gamma$, $\frac{1}{q} = \kappa\frac{1}{r} + (1 - \kappa)\frac{1}{2}$. Then by interpolation for all $t, s \in [0, T]$:

$$\begin{aligned} &\left(\mathbb{E} \left[\left\| \hat{X}_c^n(t) - \hat{X}_c^n(s) \right\|_{W^{\lambda, q}(0,1)}^2 \right] \right)^{\frac{1}{2}} \\ &\leq \left(\mathbb{E} \left[\left\| \hat{X}_c^n(t) - \hat{X}_c^n(s) \right\|_{W^{\delta, r}(0,1)}^2 \right] \right)^{\frac{\kappa}{2}} \left(\mathbb{E} \left[\left\| \hat{X}_c^n(t) - \hat{X}_c^n(s) \right\|_{-\gamma}^2 \right] \right)^{\frac{(1-\kappa)}{2}}. \end{aligned}$$

We use (2.24), (2.25) and Sobolev embedding to conclude. Indeed, for any $\beta \in (0, 1/2)$, we can choose $\delta \in (0, 1/2)$, $\gamma > 2$, $r \geq 1$ and $\kappa \in (0, 1)$ such that $(\lambda - \beta)q > 1$. It follows that there exists C such that for all $s, t \in [0, T]$:

$$\left(\mathbb{E} \left[\left\| \hat{X}_c^n(t) - \hat{X}_c^n(s) \right\|_{C^\beta([0,1])}^2 \right] \right)^{\frac{1}{2}} \leq C |t - s|^{\frac{1-\kappa}{4}},$$

Finally, we can conclude by the theorem 7.2 in chapter 3 of [19] that the laws of $(\hat{X}_c^n)_{n \in \mathbb{N}}$ are tight in $\mathcal{C}(O_T)$.

□

Step 4.

We use a Lemma in [24]. This lemma allows to get the convergence of the approximated solutions in probability in any space in which these approximated solutions are tight.

Lemma 2.3 *Let $\{Z_n\}_{n \geq 1}$ be a sequence of random elements on a Polish space E endowed by its borel σ -algebra. Then $\{Z_n\}_{n \geq 1}$ converges in probability to an E -valued random element if and any if from every pair of subsequences $\{(Z_{n_k}^1, Z_{n_k}^2)_{k \geq 1}$, one can extract a subsequence which converges weakly to a random element supported on the diagonal $\{(x, y) \in E \times E, x = y\}$.*

For any subsequence $(n_k)_{k \in \mathbb{N}}$, we have convergence of ξ^k to a finite measure ξ on O_T along some sub-subsequence $(k_m)_{m \in \mathbb{N}}$. Let $\xi_i, i = 1, 2$ be two such limits. By the second step, and the uniqueness of the reflexion measure, we know $\zeta_1 := \xi_1 - \lambda$ and $\zeta_2 := \xi_2 - \lambda$ are equals. So the limit of $(\xi^k)_{k \in \mathbb{N}}$ is unique, and ξ^k converges to its limit ξ .

Assume $(n_k^1)_{k \in \mathbb{N}}$ and $(n_k^2)_{k \in \mathbb{N}}$ are two arbitrary subsequences. In the notations of the second step and by the third step, the process $(\hat{X}_c^{n_k^1}, \hat{X}_c^{n_k^2}, W)$ is tight in a suitable space. By Skorohod's theorem, we can find a probability space and a sequence of processes $(V_1^k, V_2^k, \mathcal{W}^k)$ such that $(V_1^k, V_2^k, \mathcal{W}^k) \rightarrow (V_1, V_2, \mathcal{W})$ almost surely in $\mathcal{C}(O_T)$, and $(V_1^k, V_2^k, \mathcal{W}^k)$ as the same distribution as

$(\hat{X}_c^{n_k^1}, \hat{X}_c^{n_k^2}, W)$ for all $k \in \mathbb{N}$. In the Skorohod's space, the approximated measures respectively converge to two contact measures ζ_1 and ζ_2 . By the second step, $(V_1, \zeta_1, \mathcal{W})$ and $(V_2, \zeta_2, \mathcal{W})$ are both weak solutions of (0.3). By uniqueness, necessarily $V_1 = V_2$ and $\zeta_1 = \zeta_2$. Therefore the subsequence $\left((\hat{X}_c^{n_k^1}, \eta^{n_k^1}, W), (\hat{X}_c^{n_k^2}, \eta^{n_k^2}, W) \right)_{k \in \mathbb{N}}$ converges in law to a process supported on the diagonal. We use Lemma 2.3 to prove that the sequence (\hat{X}_c^n, η^n, W) converges in law to (\hat{X}_c, η, W) stationary weak solution of (0.3). Moreover by pathwise uniqueness and existence of strong solutions, we obtain that every weak solution is also a strong solution. \square

Proof in negative α -power case:

We again split the proof in four steps.

Step 1.

Let us assume that $(n_k)_{k \in \mathbb{N}}$ is a subsequence such that $(\hat{X}_c^{n_k})_{n \in \mathbb{N}}$ converges in law in $\mathcal{C}(O_T)$ to a process \hat{X}_c .

By Skorohod's theorem, we can find a probability space and a sequence of processes $(V^k, \mathcal{W}^k)_{k \in \mathbb{N}}$ on that probability space such that $(V^k, \mathcal{W}^k) \rightarrow (V, \mathcal{W})$ in $\mathcal{C}(O_T)$ almost surely and (V^k, \mathcal{W}^k) has the same distribution as $(\hat{X}_c^{n_k}, \mathcal{W})$ for all $k \in \mathbb{N}$. Notice that $V \geq 0$ almost surely since for all $t \leq T$ the law of $V(t, \cdot)$ is ν_c which is concentrated on K . Let now ξ^k be the following measure on O_T :

$$d\xi^k := f_\alpha^{n_k}(V^k(t, \theta)) dt d\theta.$$

Let $y \in D(A)$ with $\bar{y} = 0$, taking $h \in D(A^2)$ such that $y = Ah$ as a test function in (b) of Definition 1.1, we deduce that, for all $0 \leq t \leq T$,

$$\langle y, \xi^k \rangle_{O_t} \text{ has a limit when } k \rightarrow +\infty. \quad (2.26)$$

Like in the logarithmic case, we now prove that the total mass $\xi^n(O_T)$ is bounded. Let us denote by :

$$M_T(h) = \sup_{k \in \mathbb{N}} \left| \langle h, \xi^k \rangle_{O_T} \right| \quad (2.27)$$

for $h \in D(A)$ such that $\bar{h} = 0$. By (2.26), we know that M_T is well defined. Therefore by Lemma 2.2 it suffices to find a function w , such that $\overline{w(t, \cdot)} = c_T > 0$, and a sequence $(w^k)_{k \in \mathbb{N}}$ such that for a positive constant m_T , w^k converges uniformly to w such that

$$\langle w^k, \xi^k \rangle_{O_T} \leq m_T. \quad (2.28)$$

Denote by $w^k := ((V^k)^+ + 1/n_k)^\alpha$, it converges uniformly to $w := V^\alpha$. Since $w^k f_\alpha^{n_k}(V^k(t, \theta)) = 1$, (2.28) holds with $m_T = T$. As in the logarithmic case, by Fatou Lemma, it follows that almost surely $f_\alpha(V) \in L^1(O_T)$. \square

Step 2. We again assume that we have $(n_k)_{k \in \mathbb{N}}$ a subsequence such that $(\hat{X}_c^{n_k})_{k \in \mathbb{N}}$ converges in law to a process \hat{X}_c . Again, by Skorohod's theorem, we can find a probability space and a sequence of processes $(V^k, \mathcal{W}^k)_{k \in \mathbb{N}}$ such that almost surely $(V^k, \mathcal{W}^k) \rightarrow (V, \mathcal{W})$ in $\mathcal{C}(O_T)$ as k grows to infinity, and (V^k, \mathcal{W}^k) has the same distribution as $(\hat{X}_c^{n_k}, \mathcal{W})$ for all $k \in \mathbb{N}$. By step 1, the total mass $\xi^k(O_T)$ is bounded and there exists $(n_{k_m})_{m \in \mathbb{N}}$ a sub-subsequence such that the measures

$$\xi^{k_m} := f_\alpha^{n_{k_m}}(V^{k_m}(t, \theta)) \mathbf{1}_{V^{k_m} < 1} dt d\theta$$

converges to a measure ξ .

We denote by λ the following measure:

$$d\lambda := f_\alpha(V(t, \theta)) dt d\theta, \quad (2.29)$$

and $\zeta^m := \xi^m - \lambda$. Thus ζ^m converges to the measure $\zeta := \xi - \lambda$. Thanks to Fatou Lemma, ζ is a positive measure. Taking the limit as m grows to infinity in the approximated equation, we obtain that for all $h \in D(A^2)$ and for all $0 \leq t \leq T$:

$$\begin{aligned} \langle V(t, \cdot), h \rangle &= \langle x, h \rangle - \int_{O_t} V(s, \theta) A^2 h(\theta) ds d\theta - \int_{O_t} f_\alpha(V(s, \theta)) A h(\theta) ds d\theta \\ &\quad - \langle Ah, \zeta \rangle_{O_t} - \int_0^t \langle Bh, dW \rangle. \end{aligned}$$

This is the expected equation. Let us now show that the contact condition holds for (V, ζ) .

Case 1 : $0 \leq \alpha < 1$.

As in the second step of the logarithmic case, fix $\beta > 0$, so there exists $\varepsilon > 0$ such that $T\varepsilon^{1-\alpha} \leq \beta$. Let us define the following measures for all $m \in \mathbb{N}$:

$$\begin{aligned} d\xi_\varepsilon^m &:= f_\alpha^{n_{k_m}}(V^{k_m}(t, \theta)) \mathbb{1}_{V^{k_m} < \varepsilon} dt d\theta, & d\tau_\varepsilon^m &:= f_\alpha^{n_{k_m}}(V^{k_m}(t, \theta)) \mathbb{1}_{\varepsilon \leq V^{k_m}} dt d\theta, \\ d\lambda_\varepsilon &:= f_\alpha(V(t, \theta)) \mathbb{1}_{V < \varepsilon} dt d\theta, & d\tau_\varepsilon &:= f_\alpha(V(t, \theta)) \mathbb{1}_{\varepsilon \leq V} dt d\theta. \end{aligned}$$

Since τ_ε^m converges to τ_ε , we have

$$\begin{aligned} \limsup_{m \rightarrow +\infty} \langle V^{k_m}, \zeta^m \rangle_{O_T} &= \limsup_{m \rightarrow +\infty} \left(\langle V^{k_m}, \xi_\varepsilon^{k_m} \rangle_{O_T} - \langle V^{k_m}, \lambda_\varepsilon \rangle_{O_T} + \langle V^{k_m}, \tau_\varepsilon^m \rangle_{O_T} - \langle V^{k_m}, \tau_\varepsilon \rangle_{O_T} \right) \\ &= \limsup_{m \rightarrow +\infty} \left(\int_{O_T} V^{k_m} f_\alpha^{n_{k_m}}(V^{k_m}) \mathbb{1}_{V^{k_m} < \varepsilon} dt d\theta - \int_{O_T} V^{k_m} f_\alpha(V) \mathbb{1}_{V < \varepsilon} dt d\theta \right) \\ &\leq \limsup_{m \rightarrow +\infty} \left(\int_{O_T} V^{k_m} f_\alpha^{n_{k_m}}(V^{k_m}) \mathbb{1}_{0 \leq V^{k_m} < \varepsilon} dt d\theta \right) \\ &\quad + \limsup_{m \rightarrow +\infty} \left(\int_{O_T} (V^{k_m})^- f_\alpha(V) \mathbb{1}_{V < \varepsilon} dt d\theta \right). \end{aligned}$$

It follows

$$\begin{aligned} \limsup_{m \rightarrow +\infty} \langle V^{k_m}, \zeta^m \rangle_{O_T} &\leq T \limsup_{m \rightarrow +\infty} \sup_{x \in [0, \varepsilon]} \left| \frac{x}{\left(x + \frac{1}{n_{k_m}}\right)^\alpha} \right| \\ &\leq T \limsup_{m \rightarrow +\infty} \left| \frac{\varepsilon}{\left(\varepsilon + \frac{1}{n_{k_m}}\right)^\alpha} \right| \\ &\leq T\varepsilon^{1-\alpha}. \end{aligned}$$

Thus the contact condition holds.

Case 2 : $\alpha \geq 1$.

Let $\gamma > 0$, we prove that for all nonnegative β , $0 \leq \langle V^{\alpha+\gamma}, \zeta \rangle_{O_T} \leq \beta$ and conclude that the contact condition holds by Hölder inequality.

Fix $\beta > 0$, so there exists $\varepsilon > 0$ such that $T\varepsilon^\gamma \leq \beta$. Let us define the following measures for all $m \in \mathbb{N}$:

$$\begin{aligned} d\xi_\varepsilon^m &:= f_\alpha^{n_{k_m}}(V^{k_m}(t, \theta)) \mathbb{1}_{V^{k_m} < \varepsilon} dt d\theta, & d\tau_\varepsilon^m &:= f_\alpha^{n_{k_m}}(V^{k_m}(t, \theta)) \mathbb{1}_{\varepsilon \leq V^{k_m}} dt d\theta, \\ d\lambda_\varepsilon &:= f_\alpha(V(t, \theta)) \mathbb{1}_{V < \varepsilon} dt d\theta, & d\tau_\varepsilon &:= f_\alpha(V(t, \theta)) \mathbb{1}_{\varepsilon \leq V} dt d\theta. \end{aligned}$$

Since τ_ε^m converges to τ_ε , we have

$$\begin{aligned}
\limsup_{m \rightarrow +\infty} \langle (V^{k_m})^{\alpha+\gamma}, \zeta^m \rangle_{O_T} &= \limsup_{m \rightarrow +\infty} \left(\langle (V^{k_m})^{\alpha+\gamma}, \xi_\varepsilon^{k_m} \rangle_{O_T} - \langle (V^{k_m})^{\alpha+\gamma}, \lambda_\varepsilon \rangle_{O_T} \right. \\
&\quad \left. + \langle (V^{k_m})^{\alpha+\gamma}, \tau_\varepsilon^m \rangle_{O_T} - \langle (V^{k_m})^{\alpha+\gamma}, \tau_\varepsilon \rangle_{O_T} \right) \\
&= \limsup_{m \rightarrow +\infty} \left(\int_{O_T} (V^{k_m})^{\alpha+\gamma} f_\alpha^{n_{k_m}}(V^{k_m}) \mathbb{1}_{V^{k_m} < \varepsilon} dt d\theta \right. \\
&\quad \left. - \int_{O_T} (V^{k_m})^{\alpha+\gamma} f_\alpha(V) \mathbb{1}_{V < \varepsilon} dt d\theta \right) \\
&\leq \limsup_{m \rightarrow +\infty} \left(\int_{O_T} (V^{k_m})^{\alpha+\gamma} f_\alpha^{n_{k_m}}(V^{k_m}) \mathbb{1}_{0 \leq V^{k_m} < \varepsilon} dt d\theta \right) \\
&\quad + \limsup_{m \rightarrow +\infty} \left(\int_{O_T} ((V^{k_m})^-)^{\alpha+\gamma} f_\alpha(V) \mathbb{1}_{V < \varepsilon} dt d\theta \right).
\end{aligned}$$

It follows

$$\begin{aligned}
\limsup_{m \rightarrow +\infty} \langle (V^{k_m})^{\alpha+\gamma}, \zeta^m \rangle_{O_T} &\leq T \limsup_{m \rightarrow +\infty} \sup_{x \in [0, \varepsilon]} \left| \frac{x^{\alpha+\gamma}}{\left(x + \frac{1}{n_{k_m}}\right)^\alpha} \right| \\
&\leq T \limsup_{m \rightarrow +\infty} \left| \frac{\varepsilon^{\alpha+\gamma}}{\left(\varepsilon + \frac{1}{n_{k_m}}\right)^\alpha} \right| \\
&\leq T \varepsilon^\gamma.
\end{aligned}$$

Thus the contact condition holds. □

Step 3 and step 4 are strictly identical to the logarithmic case and we do not repeat them. This ends the proof of Theorem 2.1. Now we give the proof of the Lemma 2.2.

Proof of the Lemma 2.2:

We prove this Lemma thanks to the previous Lemma 2.1. If $\mu^k(O_T)$ is bounded uniformly for $k \in \mathbb{N}$, then the constant

$$\tilde{M}_T = \sup_{k \in \mathbb{N}} \mu^k(O_T) \quad (2.30)$$

satisfies (2.16). Suppose $\mu^k(O_T)$ is unbounded, then there exists $k_0 \in \mathbb{N}$ such that $\mu^k(O_T) > 0$ for all $k \geq k_0$, we denote for all $k \geq k_0$

$$\nu^k := \mu^k / \mu^k(O_T).$$

$\{\nu^k\}_{k \geq k_0}$ is a sequence of probability measure on O_T , and we can extract a subsequence $\{\nu^{k_m}\}_{m \in \mathbb{N}}$ such that there exists a probability measure ν with $\nu^{k_m} \rightharpoonup \nu$ when m grows to infinity. Therefore, by the uniform convergence of w^k

$$\langle w^{k_m}, \nu^{k_m} \rangle_{O_T} \xrightarrow{l \rightarrow +\infty} \langle w, \nu \rangle_{O_T}. \quad (2.31)$$

And by the uniform boundedness in (2.15), we have

$$\langle w^{k_m}, \nu^{k_m} \rangle_{O_T} \leq \frac{m_T}{\mu^{k_m}(O_T)} \xrightarrow{l \rightarrow +\infty} 0, \quad (2.32)$$

therefore

$$\langle w, \nu \rangle_{O_T} = 0. \quad (2.33)$$

Moreover, for all $h \in D(A)$ such that $\bar{h} = 0$

$$\langle h, \nu^{k_m} \rangle_{O_T} \xrightarrow{l \rightarrow +\infty} \langle h, \nu \rangle_{O_T}, \quad (2.34)$$

and by the uniform boundedness in (2.13), for all $h \in D(A)$ such that $\bar{h} = 0$, we have

$$\langle h, \nu^{k_m} \rangle_{O_T} \leq \frac{M_T(h)}{\mu^{k_m}(O_T)} \xrightarrow{l \rightarrow +\infty} 0. \quad (2.35)$$

So that for all $h \in D(A)$ such that $\bar{h} = 0$, we have

$$\langle h, \nu \rangle_{O_T} = 0. \quad (2.36)$$

Since ν is a probability measure, we deduce that (2.36) holds in fact for any $h \in \mathcal{C}(O_T)$ such that $\bar{h} = 0$. The hypothesis of Lemma 2.1 are satisfied, and we can conclude that the measure ν is null. This is a contradiction since ν is a probability measure. Then the sequence $\mu^k(O_T)$ is bounded uniformly for $k \in \mathbb{N}$, and the constant \tilde{M}_T in (2.30) fulfills (2.16). \square

2.4 Convergence of the semigroup

First we state the following result which is a corollary of Theorem 2.1.

Corollary 2.1 *Let $c > 0$.*

i) There exists a continuous process $(X(t, x), t \geq 0, x \in K \cap H_c)$ with $X(0, x) = x$ and a set K_0 dense in $K \cap H_c$, such that for all $x \in K_0$ there exists a unique strong solution of equation (0.3) given by $((X(t, x))_{t \geq 0}, \eta^x, W)$.

ii) The law of $(X(t, x)_{t \geq 0}, \eta^x)$ is a regular conditional distribution of the law of (\hat{X}_c, η) given $\hat{X}_c(0) = x \in K \cap H_c$.

Proof : By Theorem 2.1, we have a stationary strong solution \hat{X}_c in H_c , such that W and $\hat{X}_c(0)$ are independent. Conditioning (\hat{X}_c, η) on the value of $\hat{X}_c(0) = x$, with $c = \bar{x}$, we obtain for ν_c -almost every x a strong solution that we denote $(X(t, x), \eta^x)$ for all $t \geq 0$ and for all $x \in K \cap H_c$. This process is the desired process. Indeed, since the support of ν_c is $K \cap H_c$, we have a strong solution for a dense set K_0 in $K \cap H_c$.

Notice that all processes $(X(t, x))_{t \geq 0}$ with $x \in K_0$ are driven by the same noise W and are continuous with values in H . Arguing as in the proof of Lemma 2.1 we see that for all $x, y \in K_0$, for all $t \geq 0$:

$$\|X(t, x) - X(t, y)\|_{-1} \leq \|x - y\|_{-1}.$$

Then by density, we obtain a continuous process $(X(t, x))_{t \geq 0}$ in H_c for all $x \in K \cap H_c$. \square

We want to prove that for any deterministic initial condition $x \in K \cap H_c$ where $c > 0$, there exists a strong solution of equation (0.3), necessarily unique and that the process X constructed in Corollary 2.1 is a realization of such solution. We have proved this result only for x in a dense set K_0 , but thanks to the convergence of the transition semigroup $P^{n,c}$, we will be able to conclude. First we prove that the transition semigroup converges on $K \cap H_c$. This result is explained by the following proposition :

Proposition 2.3 *Let $c > 0$, for all $\phi \in \mathcal{C}_b(H)$ and $x \in K \cap H_c$:*

$$\lim_{n \rightarrow +\infty} P_t^{n,c} \phi(x) = \mathbb{E}[\phi(X(t, x))] =: P_t^c \phi(x). \quad (2.37)$$

Moreover the Markov process $(X(t, x), t \geq 0, x \in K \cap H_c)$ is strong Feller and its transition semigroup P^c is such that:

$$|P_t^c \phi(x) - P_t^c \phi(y)| \leq \frac{\|\phi\|_\infty}{\sqrt{t}} \|x - y\|_H, \quad \text{for all } x, y \in K \cap H_c, \text{ for all } t > 0. \quad (2.38)$$

Proof : By proposition 2.1 X^n is strong Feller on H_c and for all $\phi : H_c \rightarrow \mathbb{R}$ bounded and Borel we have :

$$|P_t^{n,c}\phi(x) - P_t^{n,c}\phi(y)| \leq \frac{\|\phi\|_\infty}{\sqrt{t}} \|x - y\|_H, \quad \text{for all } x, y \in K \cap H_c, \text{ for all } t > 0. \quad (2.39)$$

Since $(\nu_c^n)_{n \geq 1}$ is tight in H_c , then there exists an increasive sequence of compact sets $(J^p)_{p \in \mathbb{N}}$ in H such that:

$$\lim_{p \rightarrow +\infty} \sup_{n \geq 1} \nu_c^n(H \setminus J^p) = 0. \quad (2.40)$$

Set $J := \bigcup_{p \in \mathbb{N}} J^p \cap K$. Since the support of ν_c is in $K \cap H_c$ and $\nu_c(J) = 1$, then J is dense in $K \cap H_c$. Fix $t > 0$, by (2.39), for any $\phi \in \mathcal{C}_b(H)$:

$$\sup_{n \in \mathbb{N}} (\|P_t^{n,c}\phi\|_\infty + [P_t^{n,c}\phi]_{Lip(H_c)}) < +\infty. \quad (2.41)$$

Let $(n_j)_{j \in \mathbb{N}}$ be any sequence in \mathbb{N} . With a diagonal procedure, by Arzelà-Ascoli Theorem, there exists $(n_{j_l})_{l \in \mathbb{N}}$ a subsequence and a function $\Theta_t : J \rightarrow \mathbb{R}$ such that:

$$\lim_{l \rightarrow +\infty} \sup_{x \in J^p} |P_t^{n_{j_l},c}\phi(x) - \Theta_t(x)| = 0, \quad \text{for all } p \in \mathbb{N}. \quad (2.42)$$

By density, Θ_t can be extended uniquely to a bounded Lipschitz function $\tilde{\Theta}_t$ on $K \cap H_c$ such that

$$\tilde{\Theta}_t(x) = \lim_{l \rightarrow +\infty} P_t^{n_{j_l},c}\phi(x), \quad \text{for all } x \in K \cap H_c. \quad (2.43)$$

Note that the subsequence depends on t . Therefore, we have to prove that the limit defines a semigroup and does not depend on the chosen subsequence.

By the theorem 2.1, we have for all $\phi, \psi \in \mathcal{C}_b(H)$:

$$\begin{aligned} \mathbb{E} \left[\psi \left(\hat{X}_c(0) \right) \phi \left(\hat{X}_c(t) \right) \right] &= \lim_{l \rightarrow +\infty} \mathbb{E} \left[\psi \left(\hat{X}_c^{n_{j_l}}(0) \right) \phi \left(\hat{X}_c^{n_{j_l}}(t) \right) \right] \\ &= \lim_{l \rightarrow +\infty} \int_H \psi(y) \mathbb{E} \left[\phi \left(\hat{X}_c^{n_{j_l}}(t) \right) \mid \hat{X}_c^{n_{j_l}}(0) = y \right] \nu_c^{n_{j_l}}(dy) \\ &= \lim_{l \rightarrow +\infty} \int_H \psi(y) P_t^{n_{j_l},c}\phi(y) \nu_c^{n_{j_l}}(dy) \\ &= \int_H \psi(y) \tilde{\Theta}_t(y) \nu_c(dy). \end{aligned}$$

Thus, by Corollary 2.1, we have the following equality:

$$\mathbb{E}[\phi(X(t, x))] = \tilde{\Theta}_t(x), \quad \text{for } \nu_c\text{-almost every } x. \quad (2.44)$$

Since $\mathbb{E}[\phi(X(t, \cdot))]$ and $\tilde{\Theta}_t$ are continuous on $K \cap H_c$, and $\nu_c(K \cap H_c) = 1$, the equality (2.44) is true for all $x \in K \cap H_c$. Moreover the limit does not depend on the chosen subsequence, and we obtain (2.37). Since the semigroups are equi-Lipschitz, we deduce (2.38). \square

2.5 Existence of solutions

We have proved that there exists a continous process X which is a strong solution of equation (0.3) for an x in a dense space. In this section, we prove existence for an initial condition in $K \cap H_c$ with $c > 0$.

Theorem 2.2 *Let ξ be a K -valued random value with $\bar{\xi} > 0$ almost surely and (ξ, W) independent, then there exists a continuous process denoted $(X(t, \xi))_{t \geq 0}$ and a measure η^ξ such that:*

(a) *$((X(t, \xi))_{t \geq 0}, \eta^\xi, W)$ is the unique strong solution of (0.3) with $X(0, \xi) = \xi$ almost surely.*

- (b) The Markov process $(X(t, x), t \geq 0, x \in K \cap H_c)$ is continuous and has P^c for transition semigroup which is strong Feller on H_c .
- (c) For all $c > 0$, $x \in K \cap H_c$ and $0 = t_0 < t_1 < \dots < t_m$, $(X(t_i, x), i = 1, \dots, m)$ is the limit in distribution of $(X^n(t_i, x))_{i=1, \dots, m}$.
- (d) If ξ has distribution ν_c with $c > 0$, then $(X(t, \xi))_{t \geq 0}$ is equal in distribution to $(\hat{X}_c(t))_{t \geq 0}$.

Proof : By Corollary 2.1 we have a process $(X(t, x), t \geq 0, x \in K \cap H_c)$, such that for all x in a set K_0 dense in $K \cap H_c$ we have a strong solution $((X(t, x))_{t \geq 0}, \eta^x, W)$ of (0.3) with initial condition x . By proposition 2.3, we have that the Markov process X has transition semigroup P_c on H_c . The strong Feller property of P^c implies that for all $x \in K \cap H_c$ and $s > 0$ the law of $X(s, x)$ is absolutely continuous with respect to the invariant measure ν_c . Indeed, if $\nu_c(\Gamma) = 0$, then $\nu_c(P_s^c(\mathbb{1}_\Gamma)) = \nu_c(\Gamma) = 0$. So $P_s^c(\mathbb{1}_\Gamma)(x) = 0$ for ν_c -almost every x and by continuity for all $x \in K \cap H_c$.

Therefore almost surely $X(s, x) \in K_0$ for all $s > 0$ and $x \in K \cap H_c$. Fix $s > 0$, denote for all $\theta \in [0, 1]$:

$$\tilde{X} := t \mapsto X(t + s, x), \tilde{W}(\cdot, \theta) := t \mapsto W(t + s, \theta) - W(s, \theta),$$

and the measure $\tilde{\eta}^x$ such that for all $T > 0$, and for all $h \in \mathcal{C}(O_T)$:

$$\langle h, \tilde{\eta}^x \rangle_{O_T} := \int_{O_s^{T+s}} h(t - s, \theta) \eta^x(dt, d\theta)$$

So we have a process $\tilde{X} \in \mathcal{C}([0, T]; H) \cap \mathcal{C}(O_T)$ and a measure $\tilde{\eta}^x$ on O_T which is finite on $[\delta, T] \times [0, 1]$ for all $\delta \geq 0$, such that $((\tilde{X}(t, x))_{t \geq 0}, \tilde{\eta}^x, \tilde{W})$ is a strong solution of (0.3) with initial condition $X(s, x)$. By continuity $X(s, x) \rightarrow x$ in H as $s \rightarrow 0$, so $((X(t, x))_{t \geq 0}, \eta^x, W)$ is a strong solution of (0.3) with initial condition x in the sense of the definition 2.1.

Thanks to the previous results, (b), (c) and (d) are obvious.

□

3 Reflection and Revuz measures

We have proved the existence of solution to (0.3) with a reflection measure. In [37], L. Zambotti uses an integration by parts formula to prove that, in some cases, the reflection measure vanishes. Moreover, L. Zambotti proves that, in some other cases, the reflection measure does not vanish. He uses the theory of the Continuous Additive Functionals described in [20]. We adapt his arguments and prove similar results for our case.

3.1 Integration by parts formula

For all $\phi \in \mathcal{C}_b^1(H_c)$ we denote by $\partial_h \phi$ the directional derivative of ϕ along $h \in H$:

$$\partial_h \phi : x \mapsto \lim_{t \rightarrow 0} \frac{1}{t} (\phi(x + th) - \phi(x)), \quad x \in H.$$

For all $\phi \in \mathcal{C}_b^1(H)$, we have:

$$\langle \nabla \phi(x), h \rangle = \partial_h \phi(x).$$

We have the following classical result (see [16] for details): We denote by (M, \hat{M}) two independent copies of the standard Brownian meander (see [32] and [17]), and we set for all $r \in (0, 1)$:

$$\mathcal{U}_r(\theta) := \begin{cases} \sqrt{r} M\left(\frac{r-\theta}{r}\right), & \theta \in [0, r], \\ \sqrt{1-r} \hat{M}\left(\frac{\theta-r}{1-r}\right), & \theta \in]r, 1]. \end{cases} \quad (3.1)$$

The starting point is the Theorem 7.1 in [16] where the following formula has been proved for a process Y whose the law is μ .

Theorem 3.1 *For all Φ in $\mathcal{C}_b^1(H, \mathbb{R})$ and $h \in D(A)$:*

$$\begin{aligned} \mathbb{E}[\partial_h \Phi(Y) \mathbb{1}_{Y \in K}] &= -\mathbb{E}[(\langle Y, Ah \rangle - \bar{Y} \cdot \bar{h}) \Phi(Y) \mathbb{1}_{Y \in K}] \\ &\quad - \int_0^1 h(r) \frac{1}{\sqrt{2\pi^3 r(1-r)}} \mathbb{E}[\Phi(\mathcal{U}_r) e^{-(1/2)(\bar{\mathcal{U}}_r)^2}] dr. \end{aligned} \quad (3.2)$$

We denote by $p_{\bar{\mathcal{U}}_r} : \mathbb{R}^+ \rightarrow [0, 1]$ the continuous version of the density of $\bar{\mathcal{U}}_r$. By conditioning on $\bar{Y} = c$, we obtain:

$$\begin{aligned} \mathbb{E}[\partial_{\Pi h} \Phi(Y_c) \mathbb{1}_{Y_c \in K}] &= -\mathbb{E}[\langle Y_c, Ah \rangle \Phi(Y_c) \mathbb{1}_{Y_c \in K}] \\ &\quad - \int_0^1 \Pi h(r) \frac{p_{\bar{\mathcal{U}}_r}(c)}{\pi \sqrt{r(1-r)}} \mathbb{E}[\Phi(\mathcal{U}_r) | \bar{\mathcal{U}}_r = c] dr, \end{aligned} \quad (3.3)$$

where Y_c has been defined in the section 1. Moreover, notice that we have the following classical and easy to prove integration by parts formula for the measures $(\nu_c^n)_{n \in \mathbb{N}}$. For all Φ in $\mathcal{C}_b^1(H)$ and $h \in D(A)$:

$$\int_H \partial_{\Pi h} \Phi d\nu_c^n = - \int_H \langle x, Ah \rangle \Phi(x) \nu_c^n(dx) - \int_0^1 \Pi h(r) \int_H \Phi(x) f^n(x(r)) \nu_c^n(dx) dr. \quad (3.4)$$

We define $\gamma^n : x \mapsto \frac{1}{Z_c^n} \exp(-U^n(x))$ for all $x \in H$, where Z_c^n is the constant of normalization defined in (1.12). Then $\gamma^n \in \mathcal{C}_b^1(H)$ and for all $x, h \in K$:

$$\langle \nabla \gamma^n(x), h \rangle = \gamma^n(x) \langle \nabla \log \gamma^n(x), h \rangle = \gamma^n(x) \int_0^1 h(\theta) f^n(x(\theta)) d\theta. \quad (3.5)$$

Let ϕ be in $\mathcal{C}_b^1(H)$. We use (3.3), with $\Phi = \phi \cdot \gamma^n$. So we obtain:

$$\begin{aligned} \int_H \partial_{\Pi h} (\phi \cdot \gamma^n) d\mu_c &= - \int_H \langle x, Ah \rangle \phi(x) \gamma^n(x) \mathbb{1}_{x \in K} \mu_c(dx) \\ &\quad - \int_0^1 \Pi h(r) \frac{p_{\bar{\mathcal{U}}_r}(c)}{\pi \sqrt{r(1-r)}} \mathbb{E}[\phi(\mathcal{U}_r) \gamma^n(\mathcal{U}_r) | \bar{\mathcal{U}}_r = c] dr. \end{aligned} \quad (3.6)$$

We compute the derivative of the product, and obtain:

$$\begin{aligned} \int_H (\partial_{\Pi h} \phi) \cdot \gamma^n d\mu_c &= - \int_H \left(\langle x, Ah \rangle + \langle \nabla \log \gamma^n(x), \Pi h \rangle \right) \phi(x) \gamma^n(x) \mathbb{1}_{x \in K} \mu_c(dx) \\ &\quad - \int_0^1 \Pi h(r) \frac{p_{\overline{\mathcal{U}}_r}(c)}{\pi \sqrt{r(1-r)}} \mathbb{E} [\phi(\mathcal{U}_r) \gamma^n(\mathcal{U}_r) | \overline{\mathcal{U}}_r = c] dr. \end{aligned} \quad (3.7)$$

We want to let n go to infinity. We have to study the convergence of all the terms. By section 2.2, the left-hand side converges to:

$$\int_H (\partial_{\Pi h} \phi) d\nu_c.$$

Denote now by I_r^n the following term:

$$I_r^n := \frac{p_{\overline{\mathcal{U}}_r}(c)}{\pi \sqrt{r(1-r)}} \mathbb{E} [\phi(\mathcal{U}_r) \gamma^n(\mathcal{U}_r) | \overline{\mathcal{U}}_r = c].$$

Since Z_c^n converges, there exists C such that for all $r \in (0, 1)$:

$$|I_r^n| \leq C \frac{p_{\overline{\mathcal{U}}_r}(c)}{\sqrt{r(1-r)}} \|\phi\|_\infty J_r^n$$

where J_r^n is defined by:

$$J_r^n := \mathbb{E} \left[\exp \left(- \int_0^1 F^n(\mathcal{U}_r(\theta)) d\theta \right) \right].$$

In the logarithmic case and in the negative α -power case, as in section 2.2 and by dominated convergence, we have for all $r \in (0, 1)$:

$$\lim_{n \rightarrow +\infty} J_r^n = \mathbb{E} \left[\exp \left(- \int_0^1 F(\mathcal{U}_r(\theta)) d\theta \right) \right]. \quad (3.8)$$

Therefore, in the logarithmic case and in the negative α -power case for $\alpha > 1$, since $|J_r^n| < 1$, by dominated convergence, the last term in (3.7) has a limit when n grows to infinity.

In the negative α -power case for $\alpha \leq 1$, since

$$|J_r^n| \leq \mathbb{E} \left[\exp \left(- \int_0^1 F_\alpha^1(\mathcal{U}_r(\theta)) d\theta \right) \right],$$

by dominated convergence, the last term in (3.7) has a limit when n grows to infinity.

Moreover, if $\alpha \geq 3$, by the law of the iterated logarithm, almost surely and for all $r \in (0, 1)$:

$$\int_0^1 \frac{d\theta}{(\mathcal{U}_r(\theta))^{\alpha-1}} = +\infty.$$

Thus, in this case

$$\lim_{n \rightarrow +\infty} J_r^n = 0, \quad (3.9)$$

and, by dominated convergence, the last term in (3.7) converges to 0.

Now we use the representation described in [16] in order to prove the convergence of the first term in the right-hand side of (3.7). Denote by S^n the following

$$\begin{aligned} S^n &:= - \int_H (\langle x, Ah \rangle + \langle \nabla \log \gamma^n(x), \Pi h \rangle) \phi(x) \gamma^n(x) \mathbb{1}_{x \in K} \mu_c(dx) \\ &= - \mathbb{E} [(\langle Y_c, Ah \rangle + \langle \nabla \log \gamma^n(Y_c), \Pi h \rangle) \phi(Y_c) \gamma^n(Y_c) \mathbb{1}_{Y_c \in K}] \end{aligned} \quad (3.10)$$

We use the following Theorem whose proof is in Appendix A in [16].

Theorem 3.2 For all $\Psi : \mathcal{C}([0, 1]) \rightarrow \mathbb{R}$ bounded and Borel

$$\begin{aligned}\mathbb{E}[\Psi(Y)] &= \int_{\mathbb{R}} \mathbb{E} \left[\Psi(y + \mathbf{B}) \sqrt{\frac{4}{3}} \exp \left(-\frac{1}{2} (y + \overline{\mathbf{B}})^2 + \frac{3}{8} y^2 \right) \right] \frac{\exp(-\frac{3}{8} y^2)}{\sqrt{2\pi 4/3}} dy \\ &= \int_{\mathbb{R}} \mathbb{E} [\Psi(y + \mathbf{B}) \rho(y + \mathbf{B})] dy,\end{aligned}\tag{3.11}$$

where we set $\rho : \mathcal{C}([0, 1]) \rightarrow \mathbb{R}$,

$$\rho(u) := \frac{1}{\sqrt{2\pi}} \exp \left(-\frac{1}{2} \overline{u}^2 \right).$$

Thanks to this Theorem, we can write:

$$\begin{aligned}S^n &= - \int_{\mathbb{R}} \mathbb{E} \left[(\langle y + \mathbf{B}, Ah \rangle + \langle \nabla \log \gamma^n(y + \mathbf{B}), \Pi h \rangle) \right. \\ &\quad \left. \times \phi(y + \mathbf{B}) \gamma^n(y + \mathbf{B}) \rho(y + \mathbf{B}) \mathbb{1}_{y + \mathbf{B} \in K} \middle| \overline{\mathbf{B}} = c - y \right] dy\end{aligned}$$

We set $\mathcal{V}_r = -\sqrt{r}M(1) + \mathcal{U}_r$. Notice that \mathcal{V}_r is 0 at time 0, then run backwards the path of M on $[0, r]$ and then runs the path of \hat{M} on $[r, 1]$. Almost surely since $M > 0$ on $[0, 1]$, then \mathcal{V}_r attains the minimum $-\sqrt{r}M(1)$ only at time r . Let (τ, M, \hat{M}) be an independent triple, such that τ has the arcsine law, then \mathcal{V}_τ has the same law as \mathbf{B} (see [17]). We can write:

$$\begin{aligned}S^n &= - \int_0^1 \frac{1}{\pi \sqrt{r(1-r)}} \int_{\mathbb{R}} \mathbb{E} \left[\left(\langle y + \mathcal{V}_r, Ah \rangle + \left\langle f \left(\frac{1}{n} + y + \mathcal{V}_r \right), \Pi h \right\rangle \right) \right. \\ &\quad \left. \times \phi(y + \mathcal{V}_r) \gamma \left(\frac{1}{n} + y + \mathcal{V}_r \right) \rho(y + \mathcal{V}_r) \mathbb{1}_{y + \mathcal{V}_r \in K} \middle| \overline{\mathcal{V}}_r = c - y \right] dy \, dr \\ &= - \int_0^1 \frac{1}{\pi \sqrt{r(1-r)}} \int_{\mathbb{R}} \mathbb{E} \left[\left(\langle z - \frac{1}{n} + \mathcal{V}_r, Ah \rangle + \langle f(z + \mathcal{V}_r), \Pi h \rangle \right) \right. \\ &\quad \left. \times \phi(z - \frac{1}{n} + \mathcal{V}_r) \gamma(z + \mathcal{V}_r) \rho(z - \frac{1}{n} + \mathcal{V}_r) \mathbb{1}_{z - \frac{1}{n} + \mathcal{V}_r \in K} \middle| \overline{\mathcal{V}}_r = c - z + \frac{1}{n} \right] dz \, dr.\end{aligned}$$

Now we use the proposition 3.3 which is stated in the next section 3.3. Thus, we can use Fatou Lemma to prove that for all $h \in D(A)$:

$$\frac{1}{\pi \sqrt{r(1-r)}} [\langle f(z + \mathcal{V}_r), \Pi h \rangle \|\phi\|_\infty \gamma(z + \mathcal{V}_r) \mathbb{1}_{z + \mathcal{V}_r \in K}]$$

is integrable on $\Omega \times \mathbb{R} \times [0, 1]$. Thus, we can use the dominated convergence Theorem to see:

$$\begin{aligned}\lim_{n \rightarrow +\infty} S^n &= - \int_0^1 \frac{1}{\pi \sqrt{r(1-r)}} \int_{\mathbb{R}} \mathbb{E} \left[\left(\langle z + \mathcal{V}_r, Ah \rangle + \langle f(z + \mathcal{V}_r), \Pi h \rangle \right) \right. \\ &\quad \left. \times \phi(z + \mathcal{V}_r) \gamma(z + \mathcal{V}_r) \rho(z + \mathcal{V}_r) \mathbb{1}_{z + \mathcal{V}_r \in K} \middle| \overline{\mathcal{V}}_r = c - z \right] dz \, dr \\ &= - \int_{\mathbb{R}} \mathbb{E} \left[\left(\langle z + \mathcal{V}_\tau, Ah \rangle + \langle f(z + \mathcal{V}_\tau), \Pi h \rangle \right) \right. \\ &\quad \left. \times \phi(z + \mathcal{V}_\tau) \gamma(z + \mathcal{V}_\tau) \rho(z + \mathcal{V}_\tau) \mathbb{1}_{z + \mathcal{V}_\tau \in K} \middle| \overline{\mathcal{V}}_\tau = c - z \right] dz \\ &= - \mathbb{E} \left[\left(\langle Y, Ah \rangle + \langle f(Y), \Pi h \rangle \right) \phi(Y) \gamma(Y) \mathbb{1}_{Y \in K} \middle| \overline{Y} = c \right] \\ &= - \mathbb{E} \left[\left(\langle Y_c, Ah \rangle + \langle f(Y), \Pi h \rangle \right) \phi(Y_c) \gamma(Y_c) \mathbb{1}_{Y_c \in K} \right] \\ &= - \int_H \left(\langle x, Ah \rangle + \langle f(x), \Pi h \rangle \right) \phi(x) \nu_c(dx)\end{aligned}\tag{3.12}$$

For all $r \in (0, 1)$, denote Σ_r^c such that:

$$\Sigma_r^c(d\omega) := \frac{1}{\mu_c(K)} \frac{p_{\overline{\mathcal{U}}_r}(c)}{\pi \sqrt{r(1-r)}} \mathbb{P}(\mathcal{U}_r \in d\omega | \overline{\mathcal{U}}_r = c), \quad (3.13)$$

thus we have the following Theorem:

Theorem 3.3 *For all ϕ in $\mathcal{C}_b^1(H)$ and $h \in D(A)$:*

$$\begin{aligned} \int_H \partial_{\Pi h} \phi(x) \mathbf{1}_{x \in K} \nu_c(dx) &= - \int_H \left(\langle x, Ah \rangle + \langle f(x), \Pi h \rangle \right) \phi(x) \nu_c(dx) \\ &\quad - \int_0^1 \Pi h(r) \int \phi \gamma d\Sigma_r^c dr. \end{aligned} \quad (3.14)$$

Moreover, for $\alpha \geq 3$, the last term vanishes.

3.2 Dirichlet forms

We now describe the Dirichlet Forms and the resolvent associated to \hat{X}_c^n , in order to obtain the Dirichlet Forms and the resolvent associated to \hat{X}_c . The first result is the following description of the generator of Z . Let $\psi_h : x \mapsto \exp(i(x, h)_{-1})$ for $x \in H_c$ and $h \in D(A^2)$, then the generator of Z is such that

$$L\psi_h(x) := \frac{d}{dt} \mathbb{E}[\psi_h(Z(t, x))] \Big|_{t=0} = -\frac{1}{2} \psi_h(x) \left(i(A^2 h, x)_{-1} + \|\Pi h\|_{-1}^2 \right)$$

We define for all $\phi \in \mathcal{C}_b(H_c)$ the resolvent of \hat{X}_c^n on H_c :

$$R_\lambda^{n,c} \phi(x) := \int_0^\infty e^{-\lambda t} \mathbb{E} \left[\phi(\hat{X}_c^n(t, x)) \right] dt, \quad x \in H_c, \lambda > 0. \quad (3.15)$$

We define $\text{Exp}_A(H_c) \subset \mathcal{C}_b(H_c)$ as the linear span of $\{\cos((h, \cdot)); \sin((h, \cdot)), h \in D(A^2)\}$. Then we define the symmetric bilinear form:

$$\mathcal{E}^{n,c}(\phi, \psi) := \frac{1}{2} \int_H \langle -A \nabla \phi, \nabla \psi \rangle d\nu_c^n, \quad \text{for all } \phi, \psi \in \text{Exp}_A(H). \quad (3.16)$$

The following result is standard.

Proposition 3.1 *($\mathcal{E}^{n,c}, \text{Exp}_A(H_c)$) is closable in $L^2(\nu_c^n)$: we denote by $(\mathcal{E}^{n,c}, D(\mathcal{E}^{n,c}))$ the closure. $(R_\lambda^{n,c})_{\lambda>0}$ is the resolvent associated with $\mathcal{E}^{n,c}$, that is, for all $\lambda > 0$ and $\psi \in L^2(\nu_c^n)$, $R_\lambda^{n,c} \psi \in D(\mathcal{E}^{n,c})$ and:*

$$\lambda \int_H R_\lambda^{n,c} \psi \phi d\nu_c^n + \mathcal{E}^{n,c}(R_\lambda^{n,c} \psi, \phi) = \int_H \psi \phi d\nu_c^n, \quad \text{for all } \phi \in D(\mathcal{E}^{n,c}). \quad (3.17)$$

Let $\psi_h : x \mapsto \exp(i(x, h))$ for $x \in H_c$ and $h \in D(A^2)$. By Itô formula

$$L^n \psi_h(x) := \frac{d}{dt} \mathbb{E}[\psi_h(\hat{X}_c^n(t, x))] \Big|_{t=0} = L\psi_h(x) + \frac{i}{2} \langle f^n(x), \Pi h \rangle \psi_h(x). \quad (3.18)$$

After an easy computation, we have $(L^n, \text{Exp}_A(H_c))$ is symmetric in $L^2(\nu_c^n)$ and:

$$\int_H L^n \phi \psi d\nu_c^n = -\frac{1}{2} \int_H \langle -A \nabla \phi, \nabla \psi \rangle d\nu_c^n, \quad \text{for all } \phi, \psi \in \text{Exp}_A(H_c). \quad (3.19)$$

Moreover we define for all $\phi \in \mathcal{C}_b(H_c)$ the resolvent of \hat{X}_c on $K \cap H_c$:

$$R_\lambda^c \phi(x) := \int_0^\infty e^{-\lambda t} \mathbb{E} \left[\phi \left(\hat{X}_c(t, x) \right) \right] dt, \quad x \in K \cap H_c, \lambda > 0. \quad (3.20)$$

We also define the symmetric bilinear form:

$$\mathcal{E}^c(\phi, \psi) := \frac{1}{2} \int_H \langle -A \nabla \phi, \nabla \psi \rangle d\nu_c, \quad \text{for all } \phi, \psi \in \mathcal{C}_b^1(H). \quad (3.21)$$

Proceeding as in the proposition 8.1 in [16], we can prove that for all $\phi, \psi \in \mathcal{C}_b^1(H_c)$, $\mathcal{E}^{n,c}(\phi, \psi) \rightarrow \mathcal{E}^c(\phi, \psi)$ and $R_\lambda^{n,c} \phi \rightarrow R_\lambda^c \phi$ uniformly as n grows to infinity. Let $\psi \in \mathcal{C}_b(H_c)$, we can write for all $h \in D(A^2)$:

$$\begin{aligned} \int_H \psi \phi_h d\nu_c &= \lim_{n \rightarrow +\infty} \int_H \psi \phi_h d\nu_c^n = \lim_{n \rightarrow +\infty} \int_H R_\lambda^{n,c} \psi (\lambda \phi_h - L^n \phi_h) d\nu_c^n \\ &= \int_H R_\lambda^c \psi (\lambda \phi_h - L \phi_h) d\nu_c - \frac{i}{2} \lim_{n \rightarrow +\infty} \int_H R_\lambda^{n,c} \psi(x) \phi_h(x) \langle f^n(x), \Pi h \rangle d\nu_c^n. \end{aligned} \quad (3.22)$$

Then, with the proposition 3.3 below:

$$\begin{aligned} \int_H \psi \phi_h d\nu_c &= \int_H R_\lambda^c \psi (\lambda \phi_h - L \phi_h) d\nu_c - \frac{i}{2} \int_H R_\lambda^c \psi(x) \phi_h(x) \langle f(x), \Pi h \rangle d\nu_c \\ &\quad - \frac{i}{2} \int_0^1 \Pi h(r) \int_H R_\lambda^c \psi \phi_h \gamma d\Sigma_r^c dr \\ &= \lambda \int_H R_\lambda^c \psi \phi_h d\nu_c - \frac{i}{2} \int_H R_\lambda^c \psi \phi_h \langle Ah, x \rangle d\nu_c + \frac{1}{2} \int_H R_\lambda^c \psi \phi_h \|\Pi h\|_{-1}^2 d\nu_c \\ &\quad - \frac{i}{2} \int_H R_\lambda^c \psi(x) \phi_h(x) \langle f(x), \Pi h \rangle d\nu_c - \frac{i}{2} \int_0^1 \Pi h(r) \int_H R_\lambda^c \psi \phi_h \gamma d\Sigma_r^c dr. \end{aligned} \quad (3.23)$$

Thanks to the integration by parts formula applied to $R_\lambda^c \psi \phi_h$, we have:

$$\int_H \psi \phi_h d\nu_c = \lambda \int_H R_\lambda^c \psi \phi_h d\nu_c + \mathcal{E}^c(R_\lambda^c \psi, \phi_h). \quad (3.24)$$

By linearity and by density, we obtain for all $\lambda > 0$ and $\psi \in \mathcal{C}_b(H)$:

$$\lambda \int_H R_\lambda^c \psi \phi d\nu_c + \mathcal{E}^c(R_\lambda^c \psi, \phi) = \int_H \psi \phi d\nu_c, \quad \text{for all } \phi \in \mathcal{D}, \quad (3.25)$$

where we denote $\mathcal{D} := \{R_\lambda^c \phi, \phi \in \mathcal{C}_b(H_c), \lambda > 0\}$. We use classical results from [26], and obtain the following proposition:

Proposition 3.2 *Let $c > 0$.*

- i) $(\mathcal{E}^c, \text{Exp}_A(H_c))$ is closable in $L^2(\nu_c)$: we denote by $(\mathcal{E}^c, D(\mathcal{E}^c))$ the closure.*
- ii) $(\mathcal{E}^c, D(\mathcal{E}^c))$ is a symmetric Dirichlet form such that $\text{Lip}(H_c) \subset D(\mathcal{E}^c)$ and $\mathcal{E}^c(\phi, \phi) \leq |\phi|_{L^{\text{ip}}(H_c)}^2$.*
- iii) $(R_\lambda^c)_{\lambda > 0}$ is the resolvent associated with \mathcal{E}^c , that is, for all $\lambda > 0$ and $\psi \in L^2(\nu_c)$, $R_\lambda^c \psi \in D(\mathcal{E}^c)$ and:*

$$\lambda \int_H R_\lambda^c \psi \phi d\nu_c + \mathcal{E}^c(R_\lambda^c \psi, \phi) = \int_H \psi \phi d\nu_c, \quad \text{for all } \phi \in D(\mathcal{E}^c). \quad (3.26)$$

- iv) $(P_t^c)_{t \geq 0}$ is the semigroup associated with $(\mathcal{E}^c, D(\mathcal{E}^c))$.*

3.3 Total mass of the reflection measure

We now state and prove the proposition 3.3 used above.

Proposition 3.3 *For all $\phi \in \mathcal{C}_b(H_c)$, for all $h \in D(A)$:*

$$\int_H \langle f^n(x), h \rangle \phi(x) \gamma^n(x) \mu_c(dx) \quad (3.27)$$

has a limit when n grows to infinity.

Moreover for all $0 < \delta \leq s \leq t \leq T$, $\mathbb{E}[\eta(O_{s,t})] < +\infty$.

Proof : Denote $\sigma_{r,c}^n$ the measure such that for all $r \in [0, 1]$, for all $c > 0$:

$$\sigma_{r,c}^n(dx) := f^n(x(r)) \gamma^n(x) \mu_c(dx)$$

It suffices to prove that:

$$\limsup_{n \rightarrow +\infty} \left| \int_0^1 \int_H d\sigma_{r,c}^n dr \right| < +\infty. \quad (3.28)$$

By symmetry, it suffices to prove convergence of

$$\left| \int_0^{1/2} \int_H d\sigma_{r,c}^n dr \right| < +\infty. \quad (3.29)$$

The idea is to study an integration by parts formula for the law of Y_c on the path space

$$\tilde{K} := \{h \in \mathcal{C}([0, 1]), h(\theta) \geq 0 \text{ for all } \theta \in [0, 1/2]\}.$$

The crucial tool is that, on this space, the processes that we consider have no more fixed mean, and we can have an integration by parts formula without the constraint of zero mean. We set for all $r \in (0, 1/2)$:

$$\mathcal{T}_r(\theta) := \begin{cases} \sqrt{r} M\left(\frac{r-\theta}{r}\right), & \theta \in [0, r], \\ \sqrt{\left(\frac{1}{2}-r\right)} \hat{M}\left(\frac{\theta-r}{\frac{1}{2}-r}\right), & \theta \in]r, 1/2]. \end{cases}$$

Moreover we set

$$\chi : \theta \mapsto \mathbb{1}_{[0, 1/2]}(\theta),$$

and for $u \in \mathcal{C}([0, 1/2])$

$$m(u) := \int_0^{1/2} (u(\theta) + u(1/2)) d\theta.$$

The starting point is the Lemma B.1 in [16] where the following formulae have been proved.

Lemma 3.1 *For all $\Psi : \mathcal{C}([0, 1/2]) \rightarrow \mathbb{R}$ bounded and Borel:*

$$\mathbb{E}[\Psi(Y_c)] = \sqrt{32} \mathbb{E}\left[\Psi(b + \mathbf{B}) \exp\left(-12(m(b + \mathbf{B}) - c)^2 + \frac{3}{8}b^2\right)\right] \quad (3.30)$$

$$= \int_{\mathbb{R}} \mathbb{E}[\Psi(y + \mathbf{B}) \tilde{\rho}(y + \mathbf{B})] dy, \quad (3.31)$$

where we set $\tilde{\rho} : \mathcal{C}([0, 1/2]) \rightarrow \mathbb{R}$,

$$\tilde{\rho}(u) := \sqrt{\frac{12}{\pi}} \exp(-12(m(u) - c)^2).$$

Moreover, for all $c > 0$ and $\Phi \in \mathcal{C}_b^1(L^2(0, 1/2))$:

$$\begin{aligned} \mathbb{E}[\partial_\chi \Phi(Y_c) \mathbb{1}_{Y_c \in \tilde{K}}] &= \mathbb{E}[24(m(Y_c) - c) \Phi(Y_c) \mathbb{1}_{Y_c \in \tilde{K}}] \\ &\quad - \int_0^{1/2} \sqrt{\frac{12}{\pi^3 \sqrt{r(1/2-r)}}} \mathbb{E}\left[\Phi(\mathcal{T}_r) e^{-12(m(\mathcal{T}_r) - c)^2}\right] dr. \end{aligned} \quad (3.32)$$

We have written $\Phi(Y_c)$ for $\Phi(Y_c|_{[0, 1/2]})$ with a slight abuse of notation. We set now for $n \geq 1$, $r \in (0, 1/2)$:

$$\tilde{U}^n(x) := \int_0^{1/2} F^n(x(\theta)) d\theta, \quad x \in L^2(0, 1).$$

We define $\tilde{\gamma}^n : x \mapsto \exp(-\tilde{U}^n(x))$ for all $x \in H$. Then $\tilde{\gamma}^n \in \mathcal{C}_b^1(L^2(0, 1/2))$ and for all $x, h \in \tilde{K}$:

$$\langle \nabla \tilde{\gamma}^n(x), h \rangle = \tilde{\gamma}^n(x) \langle \nabla \log \tilde{\gamma}^n(x), h \rangle = \tilde{\gamma}^n(x) \int_0^{1/2} h(\theta) f^n(x(\theta)) d\theta. \quad (3.33)$$

Moreover we define for $n \geq 1$, $r \in (0, 1/2)$ and $\Psi \in \mathcal{C}_b^1(L^2(0, 1/2))$:

$$\tilde{\Sigma}_r^{n,c}(\Psi) := \sqrt{\frac{12}{\pi^3 \sqrt{r(1/2-r)}}} \mathbb{E} \left[\Psi(\mathcal{T}_r) \tilde{\gamma}^n(\mathcal{T}_r) e^{-12(m(\mathcal{T}_r)-c)^2} \right].$$

Let ϕ be in $\mathcal{C}_b^1(L^2(0, 1/2))$. We use (3.32), with $\Phi = \phi \cdot \gamma^n$. So we obtain:

$$\int_H \partial_\chi(\phi \cdot \tilde{\gamma}^n) \mathbb{1}_{\tilde{K}} d\mu_c = \mathbb{E} [24(m(Y_c) - c) \phi(Y_c) \tilde{\gamma}^n(Y_c) \mathbb{1}_{Y_c \in \tilde{K}}] - \int_0^{1/2} \tilde{\Sigma}_r^{n,c}(\phi) dr. \quad (3.34)$$

We compute the derivative of the product, and take $\phi \equiv 1$, then we obtain:

$$\mathbb{E} [\langle \nabla \log \tilde{\gamma}^n(x), \chi \rangle \tilde{\gamma}^n(Y_c) \mathbb{1}_{Y_c \in \tilde{K}}] = \mathbb{E} [24(m(Y_c) - c) \tilde{\gamma}^n(Y_c) \mathbb{1}_{Y_c \in \tilde{K}}] - \int_0^{1/2} \tilde{\Sigma}_r^{n,c}(1) dr. \quad (3.35)$$

Define now for $n \geq 1$, $r \in (0, 1/2)$:

$$\tilde{U}(x) := \int_0^{1/2} F(x(\theta)) d\theta, \quad x \in L^2(0, 1).$$

We also define $\tilde{\gamma} : x \mapsto \exp(-\tilde{U}(x))$ for all $x \in H$. Moreover we define for $n \geq 1$, $r \in (0, 1/2)$ and $\Psi \in \mathcal{C}_b^1(L^2(0, 1/2))$:

$$\tilde{\Sigma}_r^c(\Psi) := \sqrt{\frac{12}{\pi^3 \sqrt{r(1/2-r)}}} \mathbb{E} \left[\Psi(\mathcal{T}_r) \tilde{\gamma}(\mathcal{T}_r) e^{-12(m(\mathcal{T}_r)-c)^2} \right].$$

Finally, we denote $\tilde{\sigma}_{r,c}^n$ the measure such that for all $r \in [0, 1]$, for all $c > 0$:

$$\tilde{\sigma}_{r,c}^n(dx) := f^n(x(r)) \tilde{\gamma}^n(x) \mu_c(dx)$$

We easily prove the following result:

Lemma 3.2 *For all $c > 0$:*

$$\lim_{n \rightarrow +\infty} \int_0^{1/2} \int_H d\tilde{\sigma}_{r,c}^n = \mathbb{E} [24(m(Y_c) - c) \tilde{\gamma}(Y_c) \mathbb{1}_{Y_c \in \tilde{K}}] - \int_0^{1/2} \tilde{\Sigma}_r^c(1) dr.$$

Moreover, for $\alpha \geq 3$ the last term vanishes.

We set now for $n \geq 1$:

$$\tilde{U}'^n(x) := \int_{1/2}^1 F^n(x(\theta)) d\theta = U^n(x) - \tilde{U}^n(x), \quad x \in L^2(0, 1).$$

We also define $\tilde{\gamma}^n : x \mapsto \exp(-\tilde{U}'^n(x))$ for all $x \in H$.

We notice now that we can compute explicitly the conditional distribution of Y_c given $(Y_c(\theta), \theta \in [0, 1/2])$. Indeed, we have for all $u \in \mathcal{C}([0, 1/2])$ and $\Psi \in \mathcal{C}_b(L^2(0, 1))$

$$\mathbb{E} [\Psi(Y_c) | Y_c = u \text{ on } [0, 1/2]] = \mathbb{E} [\Psi(\tilde{B}(c, u))],$$

where

$$\tilde{B}(c, u) := \begin{cases} u(\theta), & \theta \in [0, 1/2], \\ u(1/2) + \mathbf{B}_{\theta-1/2} - 12(1/2 - \theta)(\theta - 1/2) \left(\int_0^{1/2} \mathbf{B}(r) dr + m(u) - c \right), & \theta \in]1/2, 1]. \end{cases}$$

Then we have:

$$\begin{aligned} \int_0^{1/2} \int_H \Psi d\tilde{\sigma}_{r,c}^n dr &= \frac{1}{Z_c^n} \int_H \int_0^{1/2} \mathbb{E} \left[\Psi \times f^n \times \tilde{\gamma}^n \left(\tilde{B}(c, u) \right) \right] \tilde{\gamma}^n(u) \mu_c(du) dr, \\ &= \frac{1}{Z_c^n} \int_H \int_0^{1/2} \mathbb{E} \left[\Psi \times \tilde{\gamma}^n \left(\tilde{B}(c, u) \right) \right] f^n(u(r)) \tilde{\gamma}^n(u) \mu_c(du) dr, \\ &= \frac{1}{Z_c^n} \int_H \int_0^{1/2} \mathbb{E} \left[\Psi \times \tilde{\gamma}^n \left(\tilde{B}(c, u) \right) \right] \tilde{\sigma}_{r,c}^n(du). \end{aligned}$$

Arguing as in the proof of section 2.2, it is easy to conclude that the limit exists, which proves (3.29) and (3.27).

Recall η is the limit of $d\eta^n := f^n(\hat{X}_c^n(t, \theta))dtd\theta - f(\hat{X}_c(t, \theta))dtd\theta$. We just proved that for all $\delta \leq s \leq t \leq T$

$$\begin{aligned}
\mathbb{E}[\eta(O_{s,t})] &\leq \liminf_{n \rightarrow +\infty} \mathbb{E}[\eta^n(O_{s,t})] \\
&\leq \liminf_{n \rightarrow +\infty} \mathbb{E} \left[\int_{O_{s,t}} f^n(\hat{X}_c^n(u, \theta)) du d\theta \right] \\
&\leq \liminf_{n \rightarrow +\infty} \int_H \int_{O_{s,t}} f^n(x(\theta)) du d\theta \gamma^n(x) \mu_c(dx) \\
&= (t-s) \liminf_{n \rightarrow +\infty} \int_H \int_0^1 d\sigma_{r,c}^n dr \\
&< +\infty.
\end{aligned} \tag{3.36}$$

Thus the total mass of $O_{s,t}$ for the reflection measure η has a finite expectation. \square

3.4 Reflection and Revuz measures

Theorem 3.4 *For all $c > 0$, for all $x \in K \cap H_c$:*

- i) *For $\alpha \geq 3$, the reflection measure η^x of the strong solution $((X(t, x))_{t \geq 0}, \eta^x, W)$ vanishes.*
- ii) *For $\alpha < 3$, the reflection measure η^x of the strong solution $((X(t, x))_{t \geq 0}, \eta^x, W)$ does not vanishes.*

Proof : Let $c > 0$, $x \in K \cap H_c$, and $\alpha \geq 3$. We take the expectation of equation (0.3) for the stationary solution. We obtain for all $0 < \delta \leq s \leq t \leq T$, for all $h \in D(A^2)$:

$$\mathbb{E} \left[\int_s^t \langle \hat{X}_c(u), A^2 h \rangle du + \int_s^t \langle Ah(\theta), f(\hat{X}_c(u)) \rangle du + \langle Ah, \eta \rangle_{O_{s,t}} \right] = 0. \tag{3.37}$$

Thanks to Proposition 3.3, the expectation of each term of (3.37) is finite. So let $k \in D(A)$ with $\bar{k} = 0$, taking $h \in D(A^2)$ such that $k = Ah$ as a test function in (3.37), we obtain for all $0 < \delta \leq s \leq t \leq T$, for all $k \in D(A)$:

$$\begin{aligned}
\mathbb{E} \left[\langle \Pi k, \eta \rangle_{O_{s,t}} \right] &= -\mathbb{E} \left[\int_s^t \langle \hat{X}_c(u), Ak \rangle du + \int_s^t \langle \Pi k(\theta), f(\hat{X}_c(u)) \rangle du \right] \\
&= (s-t) \mathbb{E} \left[\langle \hat{X}_c(0), Ak \rangle + \langle \Pi k(\theta), f(\hat{X}_c(0)) \rangle \right] \\
&= (s-t) \int_H \left(\langle x, Ak \rangle + \langle f(x), \Pi k \rangle \right) \nu_c(dx).
\end{aligned}$$

We use (3.14) with $\phi = 1$, and prove that for all $k \in D(A)$, for all $0 < \delta \leq s \leq t \leq T$:

$$\mathbb{E} \left[\langle \Pi k, \eta \rangle_{O_{s,t}} \right] = 0. \tag{3.38}$$

Now, as in Lemma 2.1, $\eta \otimes \mathbb{P}$ can be decomposed as $\eta \otimes \mathbb{P} = \Gamma \otimes d\theta$, where Γ is a measure on $[0, T] \times \Omega$, so we obtain that for all $0 < \delta \leq s \leq t \leq T$, for all $\mathcal{A} \subset \Omega$:

$$0 = \mathbb{E} \left[\langle \hat{X}_c, \eta \rangle_{O_{s,t}} \mathbb{1}_{\mathcal{A}} \right] = \int_{\Omega} \left(\int_s^t \left(\int_0^1 \hat{X}_c(u)(\theta) d\theta \right) \mathbb{1}_{\mathcal{A}} \right) d\Gamma(u, \cdot) = c \times \Gamma([s, t], \mathcal{A}).$$

Since $c > 0$, we conclude that for all $0 < \delta \leq s \leq t \leq T$, for all $\mathcal{A} \subset \Omega$, $\Gamma([s, t], \mathcal{A}) = 0$. Thus $\eta \otimes \mathbb{P}$ is the null measure. Since η is a positive measure, we obtain that η is the null measure almost surely. Since the law of $(X(t, x))_{t \geq 0}, \eta^x$ is a regular conditional distribution of the law of (\hat{X}_c, η) given $\hat{X}_c(0) = x \in K \cap H_c$, we have proved i) in the Theorem 3.4.

We consider now the logarithmic case and the negative α -power case for $\alpha < 3$.

Proposition 3.4 *The process $\{X_c(t, x), t \geq 0, x \in H_c \cap K\}$ is a continuous Hunt process on K with infinite life-time and strong Markov, properly associated with the Dirichlet Form \mathcal{E}^c . In particular, \mathcal{E}^c is quasi-regular.*

The last assertion is a consequence of Theorem IV.5.1 in [26], which describes the necessity of quasi regularity of a Dirichlet Form associated with a Markov process. We now recall the definitions of the theory of Additive Functionals of a Markov process (see [20]). Consider $\{Y_c(t, x), t \geq 0, x \in H_c \cap K\}$ a Hunt process with infinite life-time and strong Markov, properly associated with the Dirichlet Form \mathcal{E}^c . We first describe the minimum admissible filtration and the minimum completed admissible filtration. We set:

$$\begin{aligned}\mathcal{F}_\infty^0 &= \sigma\{Y_c(s), s \in [0, +\infty)\}, \\ \mathcal{F}_t^0 &= \sigma\{Y_c(s), 0 \leq s \leq t\}, \quad \text{for all } 0 \leq t \leq +\infty.\end{aligned}$$

These filtrations are called the minimum admissible filtrations. We define $E := \mathcal{C}([0, T], H_c)$, and denote by \mathbb{P}_x the law of $t \mapsto Y_c(t, x)$ on the filtered space $(E, \mathcal{F}_\infty^0)$ for all $x \in H_c \cap K$. We also define \mathcal{P} the set of all probability measures on $H_c \cap K \cap \mathcal{C}([0, 1])$. For all $m \in \mathcal{P}$, we define the probability measure:

$$\begin{aligned}\mathbb{P}_m : \mathcal{F}_\infty^0 &\rightarrow \mathbb{R} \\ \Lambda &\mapsto \int_{H_c \cap K \cap \mathcal{C}([0, 1])} \mathbb{P}_x(\Lambda) m(dx).\end{aligned}$$

We then denote by \mathcal{F}_∞^m (respectively \mathcal{F}_t^m) the completion of \mathcal{F}_∞^0 (respectively the completion of \mathcal{F}_t^0 in \mathcal{F}_∞^m) with respect to \mathbb{P}_m . Finally we set

$$\mathcal{F}_\infty = \bigcap_{m \in \mathcal{P}} \mathcal{F}_\infty^m \quad \text{and} \quad \mathcal{F}_t = \bigcap_{m \in \mathcal{P}} \mathcal{F}_t^m, \quad \text{for all } 0 \leq t \leq +\infty.$$

These filtrations are the minimum completed admissible filtrations. It is now possible to define the Additive Functionals for the Markov process Y_c . To avoid useless definitions, we just recall the definition of a continuous additive functional (CAF in abreviation) in the strict sense of Y_c .

Definition 3.1 *A family of real valued functions $\mathcal{A} := (\mathcal{A}_t)_{t \geq 0}$ is called a continuous additive functionnal in the strict sense of Y_c if it satisfies the following conditions:*

- (a) \mathcal{A}_t is \mathcal{F}_t -adapted for all $t \geq 0$.
- (b) There exists $\Lambda \in \mathcal{F}_\infty$ with $\mathbb{P}_x(\Lambda) = 1$, for all $x \in H_c \cap K \cap \mathcal{C}([0, 1])$, such that $\theta_t(\Lambda) \subset \Lambda$ for all $t \geq 0$, for all $\omega \in \Lambda$, $t \mapsto \mathcal{A}_t(\omega)$ is continuous, $\mathcal{A}_0(\omega) = 0$ and for all $t, s \geq 0$:

$$A_{t+s}(\omega) = A_s(\omega) + A_t(\theta_s \omega),$$

where $(\theta_s)_{s \geq 0}$ is the time-translation semigroup on E .

Moreover, by a positive continuous additive functional (PCAF in abreviation) in the strict sense of Y_c , we mean a CAF in the strict sense of Y_c such that:

- (c) For all $\omega \in \Lambda$, $t \mapsto \mathcal{A}_t(\omega)$ is non-decreasing.

If \mathcal{A} is a linear combination of PCAFs in the strict sense of Y_c , the Revuz-measure of \mathcal{A} is a Borel signed measure m on K such that for all $\Phi, \Psi \in \mathcal{C}_b(H_c)$:

$$\int_{H_c} \Phi(x) \mathbb{E} \left[\int_0^{+\infty} \exp(-t) \Psi(Y_c(t, x)) d\mathcal{A}_t \right] \nu_c(dx) = \int_{H_c} \mathbb{E} \left[\int_0^{+\infty} \exp(-t) \Phi(Y_c(t, x)) dt \right] \Psi(x) m(dx).$$

Notice that there exists a correspondence between Revuz-measures and PCAF. We refer to Chapter 5 in [20] and Chapter VI in [26] for all basic definitions and details. In particular the definition of a martingale additive functional (MAF in abreviation), the notion of the energy of an AF, and the quasi-sets.

X_c does not satisfy suitable properties to compute Revuz-measures of PCAFs in the strict sense of X_c . Thus we will use a family of process $(Y_c^\delta)_{\delta>0}$ such that:

$$Y_c^\delta(t, x) = X_c(t + \delta, x), \quad \text{for all } x \in H_c \cap K, \text{ for all } t \geq 0, \text{ for all } \delta > 0.$$

Set $\delta > 0$. Let $k \in D(A^2)$, set $h \in D(A)$ such that $Ak = h$ and set $\mathcal{V} : H_c \cap K \mapsto \mathcal{V}(x) := \langle x, k \rangle$. Since the Dirichlet form $(\mathcal{E}_c, D(\mathcal{E}_c))$ is quasi-regular, we can apply the Fukushima decomposition (see Theorem VI.2.5 in [26]). We state that there exists a MAF of finite energy $M^{[\mathcal{V}]}$ and a CAF of zero energy $N^{[\mathcal{V}]}$ such that for \mathcal{E}^c -quasi every x :

$$\mathcal{V}(Y_c^\delta(t, x)) - \mathcal{V}(Y_c^\delta(0, x)) = M_t^{[\mathcal{V}]} + N_t^{[\mathcal{V}]}, \quad t \geq 0, \mathbb{P}_x^\delta - a.s, \quad (3.39)$$

with obvious notations for \mathbb{P}_x^δ . $M^{[\mathcal{V}]}$ and $N^{[\mathcal{V}]}$ can be extended to CAF and MAF in the strict sense of X_c , which we still denote $M^{[\mathcal{V}]}$ and $N^{[\mathcal{V}]}$, such that $M^{[\mathcal{V}]}$ is a \mathbb{P}_x -martingale and (3.39) holds for all $x \in H_c \cap K$. We have the following expression:

$$\frac{1}{2} \int_\delta^t \langle Bh, dW \rangle = M_t^{[\mathcal{V}]}(Y_c^\delta(\cdot, x)), \quad \text{for all } t \geq 0, x \in K, \text{ almost surely.}$$

Moreover $N^{[\mathcal{V}]}$ is a linear combination of PCAFs in the strict sense of Y_c^δ such that for all $t \geq 0$, $x \in K$, almost surely:

$$\frac{1}{2} \int_\delta^t (\langle X_c(s, x), Ah \rangle + \langle f(X_c(s, x), \Pi h) \rangle) ds + \frac{1}{2} \int_0^1 \Pi h(\theta) \eta^x([\delta, t], d\theta) = N_t^{[\mathcal{V}]}(Y_c^\delta(\cdot, x))$$

and its Revuz measure is:

$$\frac{1}{2} (\langle z, Ah \rangle + \langle f(z), \Pi h \rangle) \nu_c(dz) + \frac{1}{2} \int_0^1 \Pi h(r) dr \gamma d\Sigma_r^c. \quad (3.40)$$

To prove the last assertion, it suffices to remark that for all $\Phi, \Psi \in \mathcal{C}_b(H_c)$:

$$\begin{aligned} & 2 \int_{H_c} \Phi(x) \mathbb{E} \left[\int_0^{+\infty} \exp(-t) \Psi(Y_c^\delta(t, x)) dN_t^{[\mathcal{V}]} \right] \nu_c(dx) \\ &= \int_{H_c} \Psi(x) \mathbb{E} \left[\int_0^{+\infty} \exp(-t) \Phi(Y_c^\delta(t)) dt \right] \left(\langle x, Ah \rangle + \langle f(x), \Pi h \rangle + \int_0^1 \Pi h(r) dr \gamma d\Sigma_r^c \right) \nu_c(dx). \end{aligned}$$

Using the same arguments, we remark that there exists a CAF in the strict sense of Y_c^δ whose Revuz-measure is

$$\frac{1}{2} (\langle z, Ah \rangle + \langle f(z), \Pi h \rangle) \nu_c(dz). \quad (3.41)$$

Since X_c is a solution of the equation (0.3) in the sense of Definition 2.1, we obtain that there exists $\mathcal{A}^{[\mathcal{V}]}$ a linear combination of PCAFs in the strict sense of X_c such that:

$$\frac{1}{2} \int_0^1 \Pi h(\theta) \eta^x([\delta, t], d\theta) = \mathcal{A}_t^{[\mathcal{V}]}(Y_c^\delta(\cdot, x)), \quad \text{for all } t \geq 0, x \in K, \text{ almost surely,}$$

and its Revuz-measure is:

$$\frac{1}{2} \int_0^1 \Pi h(r) dr \gamma d\Sigma_r^c. \quad (3.42)$$

Finally, we have the following equality:

$$\int_H \mathbb{E} \left[\int_0^{+\infty} \exp(-t) \int_0^1 \Pi h(\theta) \eta^x(\delta + dt, d\theta) \right] \nu_c(dx) = \int_0^1 \int_H \Pi h(r) \gamma d\Sigma_r^c dr. \quad (3.43)$$

And the reflection measure η^x cannot be identically equal to zero.
